Field of the Invention

The present invention relates to an apparatus and method for performing electrical cardioversion/defibrillation and optional pacing of the heart via a totally subcutaneous non-transvenous system.

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a continuation-in-part of U.S. patent application entitled "SUBCUTANEOUS ONLY IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR AND OPTIONAL PACER," having Serial No. 09/663,606, filed September 18, 2000, pending, and U.S. patent application entitled "UNITARY SUBCUTANEOUS ONLY IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR AND OPTIONAL PACER," having Serial No. 09/663,607, filed September 18, 2000, pending, of which both applications are assigned to the assignee of the present application, and the disclosures of both applications are hereby incorporated by reference.

In addition, the present application is filed concurrently herewith U.S. patent application entitled "DUCKBILL-SHAPED IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR AND METHOD OF USE," U.S. patent application entitled "CERAMICS AND/OR OTHER MATERIAL INSULATED SHELL FOR ACTIVE AND NON-ACTIVE S-ICD CAN," U.S. patent application entitled "SUBCUTANEOUS ELECTRODE FOR

TO 2:380" OF 2:380"

5 TRANSTHORACIC CONDUCTION WITH IMPROVED INSTALLATION
CHARACTERISTICS," U.S. patent application entitled "SUBCUTANEOUS
ELECTRODE WITH IMPROVED CONTACT SHAPE FOR TRANSTHORACIC
CONDUCTION," U.S. patent application entitled "SUBCUTANEOUS
ELECTRODE FOR TRANSTHORACIC CONDUCTION WITH HIGHLY MANEUVERABLE
10 INSERTION TOOL," U.S. patent application entitled "SUBCUTANEOUS
ELECTRODE FOR TRANSTHORACIC CONDUCTION WITH INSERTION TOOL,"
U.S. patent application entitled "METHOD OF INSERTION AND
IMPLANTATION FOR IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR
CANISTERS," U.S. patent application entitled "CANISTER DESIGNS
15 FOR IMPLANTABLE CARDIOVERTER-DEFIBRILLATORS," U.S. patent
application entitled "RADIAN CURVED IMPLANTABLE CARDIOVERTER-
DEFIBRILLATOR CANISTER," U.S. patent application entitled
"CARDIOVERTER-DEFIBRILLATOR HAVING A FOCUSED SHOCKING AREA AND
ORIENTATION THEREOF," U.S. patent application entitled "BIPHASIC
20 WAVEFORM FOR ANTI-BRADYCARDIA PACING FOR A SUBCUTANEOUS
IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR," U.S. patent application
entitled "BIPHASIC WAVEFORM FOR ANTI-TACHYCARDIA PACING FOR A
SUBCUTANEOUS IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR," and U.S.
patent application entitled "POWER SUPPLY FOR A SUBCUTANEOUS
25 IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR," the disclosures of
which applications are hereby incorporated by reference.

BACKGROUND OF THE INVENTION

Defibrillation/cardioversion is a technique employed to counter arrhythmic heart conditions including some tachycardias in the atria and/or ventricles. Typically, electrodes are employed to stimulate the heart with electrical impulses or shocks, of a magnitude substantially greater than pulses used in cardiac pacing.

Defibrillation/cardioversion systems include body implantable electrodes and are referred to as implantable cardioverter/defibrillators (ICDs). Such electrodes can be in the form of patches applied directly to epicardial tissue, or at the distal end regions of intravascular catheters, inserted into a selected cardiac chamber. U.S. Pat. Nos. 4,603,705, 4,693,253, 4,944,300, 5,105,810, the disclosures of which are all incorporated herein by reference, disclose intravascular or transvenous electrodes, employed either alone or in combination with an epicardial patch electrode. Compliant epicardial defibrillator electrodes are disclosed in U.S. Pat. Nos. 4,567,900 and 5,618,287, the disclosures of which are incorporated herein by reference. A sensing epicardial electrode configuration is disclosed in U.S. Pat No. 5,476,503, the disclosure of which is incorporated herein by reference.

In addition to epicardial and transvenous electrodes, subcutaneous electrode systems have also been developed. For

5 example, U.S. Patent Nos. 5,342,407 and 5,603,732, the disclosures of which are incorporated herein by reference, teach the use of a pulse monitor/generator surgically implanted into the abdomen and subcutaneous electrodes implanted in the thorax. This system is far more complicated to use than current ICD
10 systems using transvenous lead systems together with an active can electrode and therefore it has o practical use. It has in fact never been used because of the surgical difficulty of applying such a device (3 incisions), the impractical abdominal location of the generator and the electrically poor sensing and
15 defibrillation aspects of such a system.

Recent efforts to improve the efficiency of ICDs have led manufacturers to produce ICDs which are small enough to be implanted in the pectoral region. In addition, advances in circuit design have enabled the housing of the ICD to form a
20 subcutaneous electrode. Some examples of ICDs in which the housing of the ICD serves as an optional additional electrode are described in U.S. Pat. Nos. 5,133,353, 5,261,400, 5,620,477, and 5,658,321 the disclosures of which are incorporated herein by reference.

25 ICDs are now an established therapy for the management of life threatening cardiac rhythm disorders, primarily ventricular fibrillation (V-Fib). ICDs are very effective at treating V-Fib, but are therapies that still require significant surgery.

5 As ICD therapy becomes more prophylactic in nature and used
in progressively less ill individuals, especially children at
risk of cardiac arrest, the requirement of ICD therapy to use
intravenous catheters and transvenous leads is an impediment to
very long term management as most individuals will begin to
10 develop complications related to lead system malfunction
sometime in the 5-10 year time frame, often earlier. In
addition, chronic transvenous lead systems, their reimplantation
and removals, can damage major cardiovascular venous systems and
the tricuspid valve, as well as result in life threatening
15 perforations of the great vessels and heart. Consequently, use
of transvenous lead systems, despite their many advantages, are
not without their chronic patient management limitations in
those with life expectancies of >5 years. The problem of lead
complications is even greater in children where body growth can
20 substantially alter transvenous lead function and lead to
additional cardiovascular problems and revisions. Moreover,
transvenous ICD systems also increase cost and require
specialized interventional rooms and equipment as well as
special skill for insertion. These systems are typically
25 implanted by cardiac electrophysiologists who have had a great
deal of extra training.

In addition to the background related to ICD therapy, the
present invention requires a brief understanding of automatic

5 external defibrillator (AED) therapy. AEDs employ the use of cutaneous patch electrodes to effect defibrillation under the direction of a bystander user who treats the patient suffering from V-Fib. AEDs can be as effective as an ICD if applied to the victim promptly within 2 to 3 minutes.

10 AED therapy has great appeal as a tool for diminishing the risk of death in public venues such as in air flight. However, an AED must be used by another individual, not the person suffering from the potential fatal rhythm. It is more of a public health tool than a patient-specific tool like an ICD.
15 Because >75% of cardiac arrests occur in the home, and over half occur in the bedroom, patients at risk of cardiac arrest are often alone or asleep and can not be helped in time with an AED. Moreover, its success depends to a reasonable degree on an acceptable level of skill and calm by the bystander user.

20 What is needed therefore, especially for children and for prophylactic long term use, is a combination of the two forms of therapy which would provide prompt and near-certain defibrillation, like an ICD, but without the long-term adverse sequelae of a transvenous lead system while simultaneously using
25 most of the simpler and lower cost technology of an AED. What is also needed is a cardioverter/defibrillator that is of simple design and can be comfortably implanted in a patient for many years.

5

SUMMARY OF THE INVENTION

One embodiment of the present invention provides a lead electrode assembly for subcutaneous implantation including an electrode; a riser coupled to the electrode; and a head coupled
10 to the riser.

BRIEF DESCRIPTION OF THE DRAWINGS

For a better understanding of the invention, reference is
15 now made to the drawings where like numerals represent similar objects throughout the figures where:

FIG. 1 is a schematic view of a Subcutaneous ICD (S-ICD) of the present invention;

FIG. 2 is a schematic view of an alternate embodiment of a
20 subcutaneous electrode of the present invention;

FIG. 3 is a schematic view of an alternate embodiment of a subcutaneous electrode of the present invention;

FIG. 4 is a schematic view of the S-ICD and lead of FIG. 1 subcutaneously implanted in the thorax of a patient;

25 FIG. 5 is a schematic view of the S-ICD and lead of FIG. 2 subcutaneously implanted in an alternate location within the thorax of a patient;

FIG. 6 is a schematic view of the S-ICD and lead of FIG. 3 subcutaneously implanted in the thorax of a patient;

5 FIG. 7 is a schematic view of the method of making a subcutaneous path from the preferred incision and housing implantation point to a termination point for locating a subcutaneous electrode of the present invention;

10 FIG. 8 is a schematic view of an introducer set for performing the method of lead insertion of any of the described embodiments;

15 FIG. 9 is a schematic view of an alternative S-ICD of the present invention illustrating a lead subcutaneously and serpiginously implanted in the thorax of a patient for use particularly in children;

20 FIG. 10 is a schematic view of an alternate embodiment of an S-ICD of the present invention;

 FIG. 11 is a schematic view of the S-ICD of FIG. 10 subcutaneously implanted in the thorax of a patient;

25 FIG. 12 is a schematic view of yet a further embodiment where the canister of the S-ICD of the present invention is shaped to be particularly useful in placing subcutaneously adjacent and parallel to a rib of a patient; and

 FIG. 13 is a schematic of a different embodiment where the
30 canister of the S-ICD of the present invention is shaped to be particularly useful in placing subcutaneously adjacent and parallel to a rib of a patient.

5 FIG. 14 is a schematic view of a Unitary Subcutaneous ICD
(US-ICD) of the present invention;

FIG. 15 is a schematic view of the US-ICD subcutaneously
implanted in the thorax of a patient;

FIG. 16 is a schematic view of the method of making a
10 subcutaneous path from the preferred incision for implanting the
US-ICD.

FIG. 17 is a schematic view of an introducer for performing
the method of US-ICD implantation; and

15 FIG. 18 is an exploded schematic view of an alternate
embodiment of the present invention with a plug-in portion that
contains operational circuitry and means for generating
cardioversion/defibrillation shock waves.

FIG. 14(a) is a side plan view of an embodiment of a lead
electrode assembly with a top-mounted fin;

20 FIG. 14(b) is a top plan view of an embodiment of a lead
electrode assembly with a top-mounted fin;

FIG. 14(c) is a side plan view of a section of the lead in
an embodiment of the lead electrode assembly;

25 FIG. 14(d) is a cross-sectional view of a filar in the lead
in an embodiment of the lead electrode assembly;

FIG. 14(e) is a cross-sectional view of the lead fastener
of an embodiment of a lead electrode assembly;

5 FIG. 14(f) is an exploded view of the lead fastener of an embodiment of a lead electrode assembly;

 FIG. 15(a) is a cross-sectional front plan view of an embodiment of a lead electrode assembly with a top-mounted fin;

10 FIG. 15(b) is a top plan view of an embodiment of a lead electrode assembly with a top-mounted fin;

 FIG. 16(a) is a perspective view of an embodiment of a lead electrode assembly with a top-mounted fin;

15 FIG. 17(a) is a cross-sectional side plan view of an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

 FIG. 17(b) is a cross-sectional side plan view of an embodiment of a lead electrode assembly with a top-mounted fin that is slope-shaped and a molded cover;

20 FIG. 17(c) is cross-sectional front plan view of an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

 FIG. 17(d) is an exploded top plan view of the lead fastener in an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

25 FIG. 17(e) is a bottom plan view of an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

 FIG. 17(f) is a side plan view of an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

5 FIG. 17(g) is a top plan view of an embodiment of a lead electrode assembly with a top-mounted fin and a molded cover;

FIG. 18(a) is a side plan view of an embodiment of a lead electrode assembly with an elongated top-mounted fin and a molded cover;

10 FIG. 18(b) is a top plan view of an embodiment of a lead electrode assembly with an elongated top-mounted fin and a molded cover;

15 FIG. 18(c) is a bottom plan view of an embodiment of a lead electrode assembly with an elongated top-mounted fin and a molded cover;

FIG. 19 is a side plan view of a lead electrode assembly demonstrating the curvature of the electrode;

20 FIG. 20(a) is a top plan view of the backing layer and electrode of an embodiment of a lead electrode assembly with a side-mounted fin;

FIG. 20(b) is a side plan view of the backing layer and electrode of an embodiment of a lead electrode assembly with a side-mounted fin;

25 FIG. 20(c) is a bottom plan view of an embodiment of a lead electrode assembly with a side-mounted fin;

FIG. 20(d) is a bottom plan view of an embodiment of a lead electrode assembly with a side-mounted fin with a slope-shape;

5 FIG. 21(a) is a side plan view of a lead electrode assembly
with a top-mounted loop;

FIG. 21(b) is a cross-sectional rear plan view of a lead
electrode assembly with a top-mounted loop;

10 FIG. 21(c) is a top plan view of a lead electrode assembly
with a top-mounted loop;

FIG. 22(a) is a top plan view of a backing layer for use in
an embodiment of a lead electrode assembly with a top-mounted
fin formed as part of the backing layer;

15 FIG. 22(b) is a top plan view of an embodiment of a lead
electrode assembly with a top-mounted fin formed as part of the
backing layer;

FIG. 22(c) is a side plan view of an embodiment of a lead
electrode assembly with a top-mounted fin formed as part of the
backing layer;

20 FIG. 22(d) is a front plan view of an embodiment of a lead
electrode assembly with a top-mounted fin formed as part of a
backing layer;

25 FIG. 22(e) is a side plan view of an embodiment of a lead
electrode assembly with a top-mounted fin formed as part of a
two-piece backing layer;

FIG. 22(f) is a front plan view of an embodiment of a lead
electrode assembly with a top-mounted fin formed as part of a
two-piece backing layer;

5 FIG. 23(a) is a front plan view of the embodiment of the
lead electrode assembly of FIG. 22(e) and (f) in an upright
position;

FIG. 23(b) is a front plan view of the embodiment of the
lead electrode assembly of FIG. 22(e) and (f) illustrating the
10 ability of the fin to fold;

FIG. 24(a) is a front plan view of an embodiment of a lead
electrode assembly with a top-mounted tube formed as part of a
backing layer;

15 FIG. 24(b) is a side plan view of an embodiment of a lead
electrode assembly with a top-mounted tube formed as part of a
backing layer;

FIG. 24(c) is a top plan view of an embodiment of a lead
electrode assembly with a top-mounted tube formed as part of a
backing layer;

20 FIG. 25(a) is a front plan view of an embodiment of a lead
electrode assembly with a top-mounted fin connected with
flexible joining material in an upright position;

FIG. 25(b) is a front plan view of an embodiment of a lead
electrode assembly with a top-mounted fin connected with
25 flexible joining material in a folded position;

FIG. 25(c) is a top plan view of an embodiment of a lead
electrode assembly with a top-mounted fin connected with
flexible joining material in an upright position;

5 FIG. 26 is a perspective view of an embodiment of a lead electrode assembly in which the appendage is a cylindrical tube;

FIG. 27 is a perspective view of an embodiment of a lead electrode assembly in which the appendage is a tube with a substantially triangular cross section;

10 FIGS. 28(a)-(d) are top plan views of embodiments of lead electrode assemblies illustrating shapes of the electrode and the lines of the lead;

FIGS. 28(e)-(h) are bottom plan views of embodiments of lead electrode assemblies illustrating shapes of the electrode;

15 FIG. 29 is a perspective view of a custom hemostat for lead electrode assembly implantation;

FIG. 30(a) is a perspective view of a patient's ribcage showing the orientation of the components in an implanted S-ICD system;

20 FIG. 30(b) is a cross-sectional side plan view of a patient's rib cage, skin, fat and the lead of the lead electrode assembly;

FIG. 31 is a front plan view illustrating the incision point for the surgery to implant the lead electrode assembly;

25 FIG. 32(a) is a cross-sectional bottom plan view of a patient along line 32(a) of FIG. 31 illustrating the creation of a subcutaneous path for implantation of the lead electrode assembly of an S-ICD system;

5 FIG. 32(b) is a perspective view of a lead electrode assembly captured by a custom hemostat;

FIG. 32(c) is a cross-sectional bottom plan view of a patient along line 32(a) of FIG. 31 illustrating the implantation of a lead electrode assembly via the subcutaneous
10 path;

FIG. 32(d) is a top view of a lead electrode assembly captured by a custom hemostat;

FIG. 33(a) is a perspective view of a rail of an embodiment of the lead electrode assembly;

15 FIG. 33(b) is a cross-sectional front plan view of an embodiment of the lead electrode assembly where the appendage is a rail;

FIG. 33(c) is a top plan view of an embodiment of the lead electrode assembly where the appendage is a rail;

20 FIG. 34 is a top view of an embodiment of the lead electrode assembly where the appendage is a rail;

FIG. 35(a) is a perspective view of a lead electrode assembly manipulation tool with a rail fork;

25 FIG. 35(b) is a top plan view of a lead electrode assembly manipulation tool with a rail fork;

FIG. 35(c) is a side plan view of a lead electrode assembly manipulation tool with a rail fork;

5 FIG. 35(d) is a top plan view of a lead electrode assembly having a rail captured by a lead electrode assembly manipulation tool with a rail fork;

 FIG. 36(a) is a cross-sectional side plan view of a lead electrode assembly with a pocket;

10 FIG. 36(b) is a top plan view of a lead electrode assembly with a pocket;

 FIG. 36(c) is a cross-sectional side plan view of a lead electrode assembly with a pocket and a fin;

15 FIG. 37(a) is a bottom plan view of a lead electrode assembly with a pocket;

 FIG. 37(b) is a top plan view of a lead electrode assembly with a pocket;

 FIG. 38(a) is a top plan view of a lead electrode assembly manipulation tool with a paddle;

20 FIG. 38(b) is a side plan view of a lead electrode assembly manipulation tool with a paddle;

 FIG. 38(c) is a top plan view of a lead electrode assembly with a pocket captured by a lead electrode assembly manipulation tool with a paddle;

25 FIG. 39(a) is a cross-sectional rear plan view of a lead electrode assembly with a first channel guide and a second channel guide;

5 FIG. 39(b) is a top plan view of a lead electrode assembly with a first channel guide and a second channel guide;

FIG. 40(a) is a top plan view of a lead electrode assembly manipulation tool with a channel guide fork;

10 FIG. 40(b) is a top plan view of a lead electrode assembly with a first channel guide and a second channel guide captured by a lead electrode assembly manipulation tool with a channel guide fork;

FIG. 41(a) is a perspective view of a subcutaneous implantable cardioverter-defibrillator kit; and

15 FIG. 41(b) is a perspective view of a hemostat illustrating the length measurement.

DETAILED DESCRIPTION

Turning now to FIG. 1, the S-ICD of the present invention is illustrated. The S-ICD consists of an electrically active canister 11 and a subcutaneous electrode 13 attached to the canister. The canister has an electrically active surface 15 that is electrically insulated from the electrode connector block 17 and the canister housing 16 via insulating area 14. The canister can be similar to numerous electrically active
20 canisters commercially available in that the canister will contain a battery supply, capacitor and operational circuitry. Alternatively, the canister can be thin and elongated to conform to the intercostal space. The circuitry will be able to monitor

5 cardiac rhythms for tachycardia and fibrillation, and if
detected, will initiate charging the capacitor and then
delivering cardioversion /defibrillation energy through the
active surface of the housing and to the subcutaneous electrode.
Examples of such circuitry are described in U.S. Patent Nos.
10 4,693,253 and 5,105,810, the entire disclosures of which are
herein incorporated by reference. The canister circuitry can
provide cardioversion/ defibrillation energy in different types
of waveforms. In the preferred embodiment, a 100 uF biphasic
waveform is used of approximately 10-20 ms total duration and
15 with the initial phase containing approximately 2/3 of the
energy, however, any type of waveform can be utilized such as
monophasic, biphasic, multiphasic or alternative waveforms as is
known in the art.

20 In addition to providing cardioversion/ defibrillation
energy, the circuitry can also provide transthoracic cardiac
pacing energy. The optional circuitry will be able to monitor
the heart for bradycardia and/or tachycardia rhythms. Once a
bradycardia or tachycardia rhythm is detected, the circuitry can
then deliver appropriate pacing energy at appropriate intervals
25 through the active surface and the subcutaneous electrode.
Pacing stimuli will be biphasic in the preferred embodiment and
similar in pulse amplitude to that used for conventional
transthoracic pacing.

5 This same circuitry can also be used to deliver low
amplitude shocks on the T-wave for induction of ventricular
fibrillation for testing S-ICD performance in treating V-Fib as
is described in U.S. Patent No. 5,129,392, the entire disclosure
of which is hereby incorporated by reference. Also the
10 circuitry can be provided with rapid induction of ventricular
fibrillation or ventricular tachycardia using rapid ventricular
pacing. Another optional way for inducing ventricular
fibrillation would be to provide a continuous low voltage, i.e.,
about 3 volts, across the heart during the entire cardiac cycle.

15 Another optional aspect of the present invention is that
the operational circuitry can detect the presence of atrial
fibrillation as described in Olson, W. et al. "Onset And
Stability For Ventricular Tachyarrhythmia Detection in an
Implantable Cardioverter and Defibrillator," Computers in
20 Cardiology (1986) pp. 167-170. Detection can be provided via R-
R Cycle length instability detection algorithms. Once atrial
fibrillation has been detected, the operational circuitry will
then provide QRS synchronized atrial
defibrillation/cardioversion using the same shock energy and
25 waveshape characteristics used for ventricular defibrillation/
cardioversion.

The sensing circuitry will utilize the electronic signals
generated from the heart and will primarily detect QRS waves.

5 In one embodiment, the circuitry will be programmed to detect only ventricular tachycardias or fibrillations. The detection circuitry will utilize in its most direct form, a rate detection algorithm that triggers charging of the capacitor once the ventricular rate exceeds some predetermined level for a fixed
10 period of time: for example, if the ventricular rate exceeds 240 bpm on average for more than 4 seconds. Once the capacitor is charged, a confirmatory rhythm check would ensure that the rate persists for at least another 1 second before discharge. Similarly, termination algorithms could be instituted that
15 ensure that a rhythm less than 240 bpm persisting for at least 4 seconds before the capacitor charge is drained to an internal resistor. Detection, confirmation and termination algorithms as are described above and in the art can be modulated to increase sensitivity and specificity by examining QRS beat-to-beat
20 uniformity, QRS signal frequency content, R-R interval stability data, and signal amplitude characteristics all or part of which can be used to increase or decrease both sensitivity and specificity of S-ICD arrhythmia detection function.

In addition to use of the sense circuitry for detection of
25 V-Fib or V-Tach by examining the QRS waves, the sense circuitry can check for the presence or the absence of respiration. The respiration rate can be detected by monitoring the impedance across the thorax using subthreshold currents delivered across

5 the active can and the high voltage subcutaneous lead electrode
and monitoring the frequency in undulation in the waveform that
results from the undulations of transthoracic impedance during
the respiratory cycle. If there is no undulation, then the
patent is not respiring and this lack of respiration can be used
10 to confirm the QRS findings of cardiac arrest. The same
technique can be used to provide information about the
respiratory rate or estimate cardiac output as described in U.S.
Patent Nos. 6,095,987, 5,423,326, 4,450,527, the entire
disclosures of which are incorporated herein by reference.

15 The canister of the present invention can be made out of
titanium alloy or other presently preferred electrically active
canister designs. However, it is contemplated that a malleable
canister that can conform to the curvature of the patient's
chest will be preferred. In this way the patient can have a
20 comfortable canister that conforms to the shape of the patient's
rib cage. Examples of conforming canisters are provided in U.S.
Patent No. 5,645,586, the entire disclosure of which is herein
incorporated by reference. Therefore, the canister can be made
out of numerous materials such as medical grade plastics,
25 metals, and alloys. In the preferred embodiment, the canister
is smaller than 60 cc volume having a weight of less than 100
gms for long term wearability, especially in children. The
canister and the lead of the S-ICD can also use fractal or

5 wrinkled surfaces to increase surface area to improve
defibrillation capability. Because of the primary prevention
role of the therapy and the likely need to reach energies over
40 Joules, a feature of the preferred embodiment is that the
charge time for the therapy, intentionally e relatively long to
10 allow capacitor charging within the limitations of device size.
Examples of small ICD housings are disclosed in U.S. Patents
Nos. 5,597,956 and 5,405,363, the entire disclosures of which
are herein incorporated by reference.

15 Different subcutaneous electrodes 13 of the present
invention are illustrated in FIGS. 1-3. Turning to FIG. 1, the
lead 21 for the subcutaneous electrode is preferably composed of
silicone or polyurethane insulation. The electrode is connected
to the canister at its proximal end via connection port 19 which
is located on an electrically insulated area 17 of the canister.
20 The electrode illustrated is a composite electrode with three
different electrodes attached to the lead. In the embodiment
illustrated, an optional anchor segment 52 is attached at the
most distal end of the subcutaneous electrode for anchoring the
electrode into soft tissue such that the electrode does not
25 dislodge after implantation.

The most distal electrode on the composite subcutaneous
electrode is a coil electrode 27 that is used for delivering the
high voltage cardioversion/ defibrillation energy across the

5 heart. The coil cardioversion/defibrillation electrode is about
5-10 cm in length. Proximal to the coil electrode are two sense
electrodes, a first sense electrode 25 is located proximally to
the coil electrode and a second sense electrode 23 is located
proximally to the first sense electrode. The sense electrodes
10 are spaced far enough apart to be able to have good QRS
detection. This spacing can range from 1 to 10 cm with 4 cm
being presently preferred. The electrodes may or may not be
circumferential with the preferred embodiment. Having the
electrodes non-circumferential and positioned outward, toward
15 the skin surface, is a means to minimize muscle artifact and
enhance QRS signal quality. The sensing electrodes are
electrically isolated from the cardioversion/defibrillation
electrode via insulating areas 29. Similar types of
cardioversion/defibrillation electrodes are currently
20 commercially available in a transvenous configuration. For
example, U.S. Patent No. 5,534,022, the entire disclosure of
which is herein incorporated by reference, discloses a
composite electrode with a coil cardioversion/defibrillation
electrode and sense electrodes. Modifications to this
25 arrangement is contemplated within the scope of the invention.
One such modification is illustrated in FIG. 2 where the two
sensing electrodes 25 and 23 are non-circumferential sensing
electrodes and one is located at the distal end, the other is

5 located proximal thereto with the coil electrode located in
between the two sensing electrodes. In this embodiment the
sense electrodes are spaced about 6 to about 12 cm apart
depending on the length of the coil electrode used. FIG. 3
illustrates yet a further embodiment where the two sensing
10 electrodes are located at the distal end to the composite
electrode with the coil electrode located proximally thereto.
Other possibilities exist and are contemplated within the
present invention. For example, having only one sensing
electrode, either proximal or distal to the coil cardioversion/
15 defibrillation electrode with the coil serving as both a sensing
electrode and a cardioversion/defibrillation electrode.

It is also contemplated within the scope of the invention
that the sensing of QRS waves (and transthoracic impedance) can
be carried out via sense electrodes on the canister housing or
20 in combination with the cardioversion/defibrillation coil
electrode and/or the subcutaneous lead sensing electrode(s). In
this way, sensing could be performed via the one coil electrode
located on the subcutaneous electrode and the active surface on
the canister housing. Another possibility would be to have only
25 one sense electrode located on the subcutaneous electrode and
the sensing would be performed by that one electrode and either
the coil electrode on the subcutaneous electrode or by the
active surface of the canister. The use of sensing electrodes

5 on the canister would eliminate the need for sensing electrodes
on the subcutaneous electrode. It is also contemplated that the
subcutaneous electrode would be provided with at least one sense
electrode, the canister with at least one sense electrode, and
if multiple sense electrodes are used on either the subcutaneous
10 electrode and/or the canister, that the best QRS wave detection
combination will be identified when the S-ICD is implanted and
this combination can be selected, activating the best sensing
arrangement from all the existing sensing possibilities.
Turning again to FIG. 2, two sensing electrodes 26 and 28 are
15 located on the electrically active surface 15 with electrical
insulator rings 30 placed between the sense electrodes and the
active surface. These canister sense electrodes could be
switched off and electrically insulated during and shortly after
defibrillation/ cardioversion shock delivery. The canister
20 sense electrodes may also be placed on the electrically inactive
surface of the canister. In the embodiment of FIG. 2, there are
actually four sensing electrodes, two on the subcutaneous lead
and two on the canister. In the preferred embodiment, the
ability to change which electrodes are used for sensing would be
25 a programmable feature of the S-ICD to adapt to changes in the
patient physiology and size (in the case of children) over time.
The programming could be done via the use of physical switches
on the canister, or as presently preferred, via the use of a

5 programming wand or via a wireless connection to program the
circuitry within the canister.

The canister could be employed as either a cathode or an
anode of the S-ICD cardioversion/defibrillation system. If the
canister is the cathode, then the subcutaneous coil electrode
10 would be the anode. Likewise, if the canister is the anode,
then the subcutaneous electrode would be the cathode.

The active canister housing will provide energy and voltage
intermediate to that available with ICDs and most AEDs. The
typical maximum voltage necessary for ICDs using most biphasic
15 waveforms is approximately 750 Volts with an associated maximum
energy of approximately 40 Joules. The typical maximum voltage
necessary for AEDs is approximately 2000-5000 Volts with an
associated maximum energy of approximately 200-360 Joules
depending upon the model and waveform used. The S-ICD of the
20 present invention uses maximum voltages in the range of about
700 to about 3150 Volts and is associated with energies of about
40 to about 210 Joules. The capacitance of the S-ICD could
range from about 50 to about 200 micro farads.

The sense circuitry contained within the canister is highly
25 sensitive and specific for the presence or absence of life
threatening ventricular arrhythmias. Features of the detection
algorithm are programmable and the algorithm is focused on the
detection of V-FIB and high rate V-TACH (>240 bpm). Although

5 the S-ICD of the present invention may rarely be used for an
actual life threatening event, the simplicity of design and
implementation allows it to be employed in large populations of
patients at modest risk with modest cost by non-cardiac
electrophysiologists. Consequently, the S-ICD of the present
10 invention focuses mostly on the detection and therapy of the
most malignant rhythm disorders. As part of the detection
algorithm's applicability to children, the upper rate range is
programmable upward for use in children, known to have rapid
supraventricular tachycardias and more rapid ventricular
45 fibrillation. Energy levels also are programmable downward in
order to allow treatment of neonates and infants.

Turning now to FIG. 4, the optimal subcutaneous placement
of the S-ICD of the present invention is illustrated. As would
be evidence to a person skilled in the art, the actual location
20 of the S-ICD is in a subcutaneous space that is developed during
the implantation process. The heart is not exposed during this
process and the heart is schematically illustrated in the
figures only for help in understanding where the canister and
coil electrode are three dimensionally located in the left mid-
25 clavicular line approximately at the level of the inframammary
crease at approximately the 5th rib. The lead 21 of the
subcutaneous electrode traverses in a subcutaneous path around
the thorax terminating with its distal electrode end at the

5 posterior axillary line ideally just lateral to the left scapula. This way the canister and subcutaneous cardioversion/defibrillation electrode provide a reasonably good pathway for current delivery to the majority of the ventricular myocardium.

10 FIG. 5 illustrates a different placement of the present invention. The S-ICD canister with the active housing is located in the left posterior axillary line approximately lateral to the tip of the inferior portion of the scapula. This location is especially useful in children. The lead 21 of the
15 subcutaneous electrode traverses in a subcutaneous path around the thorax terminating with its distal electrode end at the anterior precordial region, ideally in the inframammary crease. FIG. 6 illustrates the embodiment of FIG. 1 subcutaneously implanted in the thorax with the proximal sense electrodes 23
20 and 25 located at approximately the left axillary line with the cardioversion/defibrillation electrode just lateral to the tip of the inferior portion of the scapula.

FIG. 7 schematically illustrates the method for implanting the S-ICD of the present invention. An incision 31 is made in
25 the left anterior axillary line approximately at the level of the cardiac apex. This incision location is distinct from that chosen for S-ICD placement and is selected specifically to allow both canister location more medially in the left inframammary

5 crease and lead positioning more posteriorly via the introducer
set (described below) around to the left posterior axillary line
lateral to the left scapula. That said, the incision can be
anywhere on the thorax deemed reasonably by the implanting
physician although in the preferred embodiment, the S-ICD of the
10 present invention will be applied in this region. A
subcutaneous pathway 33 is then created medially to the
inframmary crease for the canister and posteriorly to the left
posterior axillary line lateral to the left scapula for the
lead.

15 The S-ICD canister 11 is then placed subcutaneously at the
location of the incision or medially at the subcutaneous region
at the left inframmary crease. The subcutaneous electrode 13 is
placed with a specially designed curved introducer set 40 (see
FIG. 8). The introducer set comprises a curved trocar 42 and a
20 stiff curved peel away sheath 44. The peel away sheath is
curved to allow for placement around the rib cage of the patient
in the subcutaneous space created by the trocar. The sheath has
to be stiff enough to allow for the placement of the electrodes
without the sheath collapsing or bending. Preferably the sheath
25 is made out of a biocompatible plastic material and is
perforated along its axial length to allow for it to split apart
into two sections. The trocar has a proximal handle 41 and a
curved shaft 43. The distal end 45 of the trocar is tapered to

5 allow for dissection of a subcutaneous path 33 in the patient.
Preferably, the trocar is cannulated having a central Lumen 46
and terminating in an opening 48 at the distal end. Local
anesthetic such as lidocaine can be delivered, if necessary,
through the lumen or through a curved and elongated needle
10 designed to anesthetize the path to be used for trocar insertion
should general anesthesia not be employed. The curved peel away
sheath 44 has a proximal pull tab 49 for breaking the sheath
into two halves along its axial shaft 47. The sheath is placed
over a guidewire inserted through the trocar after the
15 subcutaneous path has been created. The subcutaneous pathway is
then developed until it terminates subcutaneously at a location
that, if a straight line were drawn from the canister location
to the path termination point the line would intersect a
substantial portion of the left ventricular mass of the patient.
20 The guidewire is then removed leaving the peel away sheath. The
subcutaneous lead system is then inserted through the sheath
until it is in the proper location. Once the subcutaneous lead
system is in the proper location, the sheath is split in half
using the pull tab 49 and removed. If more than one
25 subcutaneous electrode is being used, a new curved peel away
sheath can be used for each subcutaneous electrode.

The S-ICD will have prophylactic use in adults where
chronic transvenous/epicardial ICD lead systems pose excessive

5 risk or have already resulted in difficulty, such as sepsis or
lead fractures. It is also contemplated that a major use of the
S-ICD system of the present invention will be for prophylactic
use in children who are at risk for having fatal arrhythmias,
where chronic transvenous lead systems pose significant
10 management problems. Additionally, with the use of standard
transvenous ICDs in children, problems develop during patient
growth in that the lead system does not accommodate the growth.
FIG. 9 illustrates the placement of the S-ICD subcutaneous lead
system such that the problem that growth presents to the lead
45 system is overcome. The distal end of the subcutaneous
electrode is placed in the same location as described above
providing a good location for the coil
cardioversion/defibrillation electrode 27 and the sensing
electrodes 23 and 25. The insulated lead 21, however is no
20 longer placed in a taught configuration. Instead, the lead is
serpiginously placed with a specially designed introducer trocar
and sheath such that it has numerous waves or bends. As the
child grows, the waves or bends will straighten out lengthening
the lead system while maintaining proper electrode placement.
25 Although it is expected that fibrous scarring especially around
the defibrillation coil will help anchor it into position to
maintain its posterior position during growth, a lead system
with a distal tine or screw electrode anchoring system 52 can

5 also be incorporated into the distal tip of the lead to facilitate lead stability (see FIG. 1). Other anchoring systems can also be used such as hooks, sutures, or the like.

FIGS. 10 and 11 illustrate another embodiment of the present S-ICD invention. In this embodiment there are two subcutaneous electrodes 13 and 13' of opposite polarity to the canister. The additional subcutaneous electrode 13' is essentially identical to the previously described electrode. In this embodiment the cardioversion/defibrillation energy is delivered between the active surface of the canister and the two coil electrodes 27 and 27'. Additionally, provided in the canister is means for selecting the optimum sensing arrangement between the four sense electrodes 23, 23', 25, and 25'. The two electrodes are subcutaneously placed on the same side of the heart. As illustrated in FIG. 6, one subcutaneous electrode 13 is placed inferiorly and the other electrode 13' is placed superiorly. It is also contemplated with this dual subcutaneous electrode system that the canister and one subcutaneous electrode are the same polarity and the other subcutaneous electrode is the opposite polarity.

25 Turning now to FIGS. 12 and 13, further embodiments are illustrated where the canister 11 of the S-ICD of the present invention is shaped to be particularly useful in placing subcutaneously adjacent and parallel to a rib of a patient. The

5 canister is long, thin, and curved to conform to the shape of
the patient's rib. In the embodiment illustrated in FIG. 12,
the canister has a diameter ranging from about 0.5 cm to about 2
cm without 1 cm being presently preferred. Alternatively,
instead of having a circular cross sectional area, the canister
10 could have a rectangular or square cross sectional area as
illustrated in FIG. 13 without falling outside of the scope of
the present invention. The length of the canister can vary
depending on the size of the patient's thorax. Currently the
canister is about 5 cm to about 15 cm long with about 10 being
15 presently preferred. The canister is curved to conform to the
curvature of the ribs of the thorax. The radius of the
curvature will vary depending on the size of the patient, with
smaller radiuses for smaller patients and larger radiuses for
larger patients. The radius of the curvature can range from
20 about 5 cm to about 35 cm depending on the size of the patient.
Additionally, the radius of the curvature need not be uniform
throughout the canister such that it can be shaped closer to the
shape of the ribs. The canister has an active surface, 15 that
is located on the interior (concave) portion of the curvature
25 and an inactive surface 16 that is located on the exterior
(convex) portion of the curvature. The leads of these
embodiments, which are not illustrated except for the attachment
port 19 and the proximal end of the lead 21, can be any of the

5 leads previously described above, with the lead illustrated in FIG. 1 being presently preferred.

The circuitry of this canister is similar to the circuitry described above. Additionally, the canister can optionally have at least one sense electrode located on either the active
10 surface of the inactive surface and the circuitry within the canister can be programmable as described above to allow for the selection of the best sense electrodes. It is presently preferred that the canister have two sense electrodes 26 and 28 located on the inactive surface of the canisters as illustrated,
15 where the electrodes are spaced from about 1 to about 10 cm apart with a spacing of about 3 cm being presently preferred. However, the sense electrodes can be located on the active surface as described above.

It is envisioned that the embodiment of FIG. 12 will be subcutaneously implanted adjacent and parallel to the left
20 anterior 5th rib, either between the 4th and 5th ribs or between the 5th and 6th ribs. However other locations can be used.

Another component of the S-ICD of the present invention is a cutaneous test electrode system designed to simulate the
25 subcutaneous high voltage shock electrode system as well as the QRS cardiac rhythm detection system. This test electrode system is comprised of a cutaneous patch electrode of similar surface area and impedance to that of the S-ICD canister itself together

5 with a cutaneous strip electrode comprising a defibrillation strip as well as two button electrodes for sensing of the QRS. Several cutaneous strip electrodes are available to allow for testing various bipole spacings to optimize signal detection comparable to the implantable system.

10 Figures 14 to 18 depict particular US-ICD embodiments of the present invention. The various sensing, shocking and pacing circuitry, described in detail above with respect to the S-ICD embodiments, may additionally be incorporated into the following US-ICD embodiments. Furthermore, particular aspects of any
15 individual S-ICD embodiment discussed above, may be incorporated, in whole or in part, into the US-ICD embodiments depicted in the following figures.

Turning now to Fig. 14, the US-ICD of the present invention is illustrated. The US-ICD consists of a curved housing 1211
20 with a first and second end. The first end 1413 is thicker than the second end 1215. This thicker area houses a battery supply, capacitor and operational circuitry for the US-ICD. The circuitry will be able to monitor cardiac rhythms for tachycardia and fibrillation, and if detected, will initiate
25 charging the capacitor and then delivering cardioversion/defibrillation energy through the two cardioversion/defibrillating electrodes 1417 and 1219 located on the outer surface of the two ends of the housing. The circuitry

5 can provide cardioversion/defibrillation energy in different
types of waveforms. In the preferred embodiment, a 100 uF
biphasic waveform is used of approximately 10-20 ms total
duration and with the initial phase containing approximately 2/3
of the energy, however, any type of waveform can be utilized
10 such as monophasic, biphasic, multiphasic or alternative
waveforms as is known in the art.

The housing of the present invention can be made out of
titanium alloy or other presently preferred ICD designs. It is
contemplated that the housing is also made out of biocompatible
15 plastic materials that electronically insulate the electrodes
from each other. However, it is contemplated that a malleable
canister that can conform to the curvature of the patient's
chest will be preferred. In this way the patient can have a
comfortable canister that conforms to the unique shape of the
20 patient's rib cage. Examples of conforming ICD housings are
provided in U.S. Patent No. 5,645,586, the entire disclosure of
which is herein incorporated by reference. In the preferred
embodiment, the housing is curved in the shape of a 5th rib of a
person. Because there are many different sizes of people, the
25 housing will come in different incremental sizes to allow a good
match between the size of the rib cage and the size of the US-
ICD. The length of the US-ICD will range from about 15 to about
50 cm. Because of the primary preventative role of the therapy

5 and the need to reach energies over 40 Joules, a feature of the preferred embodiment is that the charge time for the therapy, intentionally be relatively long to allow capacitor charging within the limitations of device size.

10 The thick end of the housing is currently needed to allow for the placement of the battery supply, operational circuitry, and capacitors. It is contemplated that the thick end will be about 0.5 cm to about 2 cm wide with about 1 cm being presently preferred. As microtechnology advances, the thickness of the housing will become smaller.

15 The two cardioversion/defibrillation electrodes on the housing are used for delivering the high voltage cardioversion/defibrillation energy across the heart. In the preferred embodiment, the cardioversion/defibrillation electrodes are coil electrodes, however, other
20 cardioversion/defibrillation electrodes could be used such as having electrically isolated active surfaces or platinum alloy electrodes. The coil cardioversion/defibrillation electrodes are about 5-10 cm in length. Located on the housing between the two cardioversion/defibrillation electrodes are two sense
25 electrodes 1425 and 1427. The sense electrodes are spaced far enough apart to be able to have good QRS detection. This spacing can range from 1 to 10 cm with 4 cm being presently preferred. The electrodes may or may not be circumferential

5 with the preferred embodiment. Having the electrodes non-circumferential and positioned outward, toward the skin surface, is a means to minimize muscle artifact and enhance QRS signal quality. The sensing electrodes are electrically isolated from the cardioversion/defibrillation electrode via insulating areas
10 1423. Analogous types of cardioversion/defibrillation electrodes are currently commercially available in a transvenous configuration. For example, U.S. Patent No. 5,534,022, the entire disclosure of which is herein incorporated by reference, discloses a composite electrode with a coil
15 cardioversion/defibrillation electrode and sense electrodes. Modifications to this arrangement is contemplated within the scope of the invention. One such modification is to have the sense electrodes at the two ends of the housing and have the cardioversion/defibrillation electrodes located in between the
20 sense electrodes. Another modification is to have three or more sense electrodes spaced throughout the housing and allow for the selection of the two best sensing electrodes. If three or more sensing electrodes are used, then the ability to change which electrodes are used for sensing would be a programmable feature
25 of the US-ICD to adapt to changes in the patient physiology and size over time. The programming could be done via the use of physical switches on the canister, or as presently preferred,

5 via the use of a programming wand or via a wireless connection to program the circuitry within the canister.

Turning now to Fig. 15, the optimal subcutaneous placement of the US-ICD of the present invention is illustrated. As would be evident to a person skilled in the art, the actual location of the US-ICD is in a subcutaneous space that is developed during the implantation process. The heart is not exposed during this process and the heart is schematically illustrated in the figures only for help in understanding where the device and its various electrodes are three dimensionally located in the thorax of the patient. The US-ICD is located between the left mid-clavicular line approximately at the level of the inframammary crease at approximately the 5th rib and the posterior axillary line, ideally just lateral to the left scapula. This way the US-ICD provides a reasonably good pathway for current delivery to the majority of the ventricular myocardium.

Fig. 16 schematically illustrates the method for implanting the US-ICD of the present invention. An incision 1631 is made in the left anterior axillary line approximately at the level of the cardiac apex. A subcutaneous pathway is then created that extends posteriorly to allow placement of the US-ICD. The incision can be anywhere on the thorax deemed reasonable by the implanting physician although in the preferred embodiment, the

5 US-ICD of the present invention will be applied in this region.
The subcutaneous pathway is created medially to the inframammary
crease and extends posteriorly to the left posterior axillary
line. The pathway is developed with a specially designed curved
introducer 1742 (see Fig. 17). The trocar has a proximal handle
10 1641 and a curved shaft 1643. The distal end 1745 of the trocar
is tapered to allow for dissection of a subcutaneous path in the
patient. Preferably, the trocar is cannulated having a central
lumen 1746 and terminating in an opening 1748 at the distal end.
Local anesthetic such as lidocaine can be delivered, if
15 necessary, through the lumen or through a curved and elongated
needle designed to anesthetize the path to be used for trocar
insertion should general anesthesia not be employed. Once the
subcutaneous pathway is developed, the US-ICD is implanted in
the subcutaneous space, the skin incision is closed using
20 standard techniques.

As described previously, the US-ICDs of the present
invention vary in length and curvature. The US-ICDs are
provided in incremental sizes for subcutaneous implantation in
different sized patients. Turning now to Fig. 18, a different
25 embodiment is schematically illustrated in exploded view which
provides different sized US-ICDs that are easier to manufacture.
The different sized US-ICDs will all have the same sized and
shaped thick end 1413. The thick end is hollow inside allowing

5 for the insertion of a core operational member 1853. The core member comprises a housing 1857 which contains the battery supply, capacitor and operational circuitry for the US-ICD. The proximal end of the core member has a plurality of electronic plug connectors. Plug connectors 1861 and 1863 are
10 electronically connected to the sense electrodes via pressure fit connectors (not illustrated) inside the thick end which are standard in the art. Plug connectors 1865 and 1867 are also electronically connected to the cardioverter/defibrillator electrodes via pressure fit connectors inside the thick end.
15 The distal end of the core member comprises an end cap 1855, and a ribbed fitting 1859 which creates a water-tight seal when the core member is inserted into opening 1851 of the thick end of the US-ICD.

20 The core member of the different sized and shaped US-ICD will all be the same size and shape. That way, during an implantation procedures, multiple sized US-ICDs can be available for implantation, each one without a core member. Once the implantation procedure is being performed, then the correct sized US-ICD can be selected and the core member can be inserted
25 into the US-ICD and then programmed as described above. Another advantage of this configuration is when the battery within the core member needs replacing it can be done without removing the entire US-ICD.

5 FIG. 14(a) illustrates an embodiment of the subcutaneous
lead electrode or "lead electrode assembly" 100. The lead
electrode assembly 100 is designed to provide an electrode 107
to be implanted subcutaneously in the posterior thorax of a
patient for delivery of cardioversion/defibrillation energy.
10 The lead electrode assembly 100 is further designed to provide a
path for the cardioversion/defibrillation energy to reach the
electrode 107 from the operational circuitry within the canister
11 of an S-ICD such as the embodiment shown in FIG. 1.

15 The lead electrode assembly 100 comprises a connector 111,
a lead 21, a lead fastener 146, an electrode 107 and an
appendage 118. The connector 111 is connected to the lead 21.
The lead 21 is further connected to the electrode 107 with the
lead fastener 146. The appendage 118 is mounted to the
electrode 107.

20 The connector 111 provides an electrical connection between
the lead 21 and the operational circuitry within the canister 11
of an S-ICD such as the embodiment shown in FIG. 1. Connector
111 is designed to mate with the connection port 19 on the
canister 11. In the embodiment under discussion, the connector
25 111 meets the IS-1 standard.

 The lead 21 of the lead electrode assembly 100 provides an
electrical connection between the connector 111 and the
electrode 107. The lead 21 comprises a distal end 101 and a

5 proximal end 102. The distal end 101 of the lead 21 is attached to the connector 111. The proximal end 102 of the lead 21 is attached to electrode 107 with the lead fastener 146.

The lead 21 has a lead length, l_{Lead} , measured from the connector 111 along the lead 21 to the lead fastener 146 of the electrode 107. The length of the lead 21 is approximately 25 cm. In alternative embodiments, the lead lengths range between approximately 5 cm and approximately 52 cm.

The lead fastener 146 provides a robust physical and electrical connection between the lead 21 and the electrode 107. The lead fastener 146 joins the proximal end 102 of the lead 21 to electrode 107.

The electrode 107 comprises an electrically conductive member designed to make contact with the tissue of the patient and transfer cardioversion/defibrillation energy to the tissue of the patient from the S-ICD canister 11.

The electrode 107 illustrated is generally flat and planar, comprising a top surface 110, a bottom surface 115, a distal end 103 and a proximal end 104. The lead fastener 146 is attached to the top surface 110 of the distal end 103 of the electrode 107.

The electrode 107 may have shapes other than planar. In an alternate embodiment, the electrode 107 is shaped like a coil.

5 The appendage 118 is a member attached to the electrode 107 that can be gripped and used to precisely locate the lead electrode assembly 100 during its surgical implantation within the patient.

10 The appendage 118 has a first end 105, a second end 106, a distal edge 121 and a proximal edge 129. The second end 106 of the appendage 118 is attached to the top surface 110 of the electrode 107. The appendage 118 is positioned such that its proximal edge 129 is within approximately 20 mm of the proximal end 104 of the electrode 107. In alternate embodiments, the
15 appendage 118 is attached to the electrode 107 in other positions.

It is useful at this point, to set out several general definitions for future reference in discussing the dimensions and placement of appendages 118.

20 The appendage height, $h_{\text{Appendage}}$, is defined as the distance from the point of the appendage 118 most distant from the electrode 107 to a point of the appendage 118 closest to the electrode 107 measured along a line perpendicular to the top surface 110 of the electrode 107. The appendage height of the
25 appendage 118 illustrated, for example, would be measured between the first end 105 of the appendage 118 and the second end 106 of the appendage 118.

5 The appendage height of the appendage 118 illustrated is approximately 5 mm. In alternative embodiments, the appendage heights range between approximately 1 mm and approximately 10 mm.

10 The appendage interface is defined as the part of the appendage 118 that joins it to the electrode 107. The appendage interface of the appendage 118 illustrated, for example, would be the second end 106 of the appendage 118.

15 The appendage length, $l_{\text{Appendage}}$, is the length of the appendage 118 along the appendage interface. The appendage interface of the appendage 118 illustrated, for example, would be the length of the second end 106 of the appendage 118.

20 The appendage length of the appendage 118 illustrated in FIG. 14 is approximately 1 cm. In alternative embodiments, appendage lengths range between approximately 2 mm and approximately 6 cm. In an alternate embodiment, the appendage 118 is substantially as long as the electrode 107.

More particularly, the appendage 118 of the embodiment illustrated is a fin 120 comprising a fin core 122 (phantom view) and a coating 125.

25 The fin core 122 generally provides support for the fin 120. The fin core 122 has a first end 126 and a second end 127. The second end 127 of the fin core 122 is attached to the top surface 110 of the electrode 107.

5 The fin core 122 comprises a metal selected from the group
consisting essentially of titanium, nickel alloys, stainless
steel alloys, platinum, platinum iridium, and mixtures thereof.
In other embodiments, the fin core 122 comprises any rugged
material that can be attached to the first surface 110 of the
10 electrode 107.

15 The coating 125 is disposed around the fin core 122. The
coating 125 provides a surface for the fin 120 that can be
easily gripped during the implantation of the lead electrode
assembly 100. The coating 125 covering the fin core 122 is
composed of molded silicone. In an alternative embodiment, the
coating 125 may be any polymeric material. In this
specification, the term polymeric material includes the group of
materials consisting of a polyurethane, a polyamide, a
polyeteretherketone (PEEK), a polyether block amide (PEBA), a
20 polytetrafluoroethylene (PTFE), a silicone and mixtures thereof.

25 In one embodiment, the fin 120 is reinforced with a layer
of Dacron® polymer mesh attached to the inside of the coating
125. Dacron® is a registered trademark of E.I. du Pont de
Nemours and Company Corporation, Wilmington, DE. In another
embodiment, the Dacron® polymer mesh attached to the outside of
the coating 125. In another embodiment, the fin 120 is
reinforced with a layer of any polymeric material.

5 FIG. 14(b) illustrates a top view of the lead electrode assembly 100. The electrode 107 is substantially rectangular in shape, comprising a first pair of sides 108, a second pair of sides 109 and four corners 112. In an alternative embodiment the electrode 107 has a shape other than rectangular. In this
10 embodiment, the corners 112 of the electrode 107 are rounded. In an alternative embodiment the corners 112 of the electrode 107 are not rounded.

15 The first pair of sides 108 of the electrode 107 are substantially linear, substantially parallel to each other and are approximately 1 cm in length. The second pair of sides 109 of the electrode 107 are also substantially linear, substantially parallel with each other and are approximately 5 cm in length. The bottom surface 115 of the electrode 107 has an area of approximately 500 square mm. In alternative
20 embodiments, the first pair of sides 108 and the second pair of sides 109 of the electrode 107 are neither linear nor parallel.

25 In alternative embodiments, the length of the first pair of sides 108 and second pair of sides 109 of the electrode 107 range independently between approximately 1 cm and approximately 5 cm. The surface area of the bottom surface 115 of the electrode 107 ranges between approximately 100 sq. mm and approximately 2000 sq. mm. In one embodiment, the first pair of sides 108 and second pair of sides 109 of the electrode 107 are

5 linear and of equal length, such that the electrode 107 is substantially square-shaped.

The electrode 107 comprises a sheet of metallic mesh 114 further comprised of woven wires 119. The metallic mesh 114 comprises a metal selected from the group consisting essentially
10 of titanium, nickel alloys, stainless steel alloys, platinum, platinum iridium, and mixtures thereof. In other embodiments, the metallic mesh 114 comprises any conductive material.

In an alternate embodiment, the electrode 107 comprises a solid metallic plate. The metallic plate comprises a metal
15 selected from the group consisting essentially of titanium, nickel alloys, stainless steel alloys, platinum, platinum iridium, and mixtures thereof. In other embodiments, the solid plate comprises any conductive material.

The metallic mesh 114 is approximately a 150 mesh, having
20 approximately 150 individual wires 119 per inch. In alternative embodiments, the metallic mesh 114 ranges between approximately a 50 mesh and approximately a 200 mesh. In this embodiment, the diameter of the wires 119 of the mesh is approximately 1 mil. In alternative embodiments, the diameter of the wires 119 ranges
25 between approximately 1 and approximately 5 mils.

The metallic mesh 114 is first prepared by spot welding together the wires 119 located along the first pair of sides 108 and second pair of sides 109 of the metallic mesh 114. The

5 excess lengths of wires are then ground or machined flush, so as to produce a smooth edge and to form a smooth border 113. In an alternate embodiment, the wires 119 located along the first pair of sides 108 and second pair of sides 109 of the metallic mesh 114 are bent in toward the metallic mesh 114 to form a smooth
10 border 113.

The fin 120 is attached to the top surface 110 of the electrode 107 in a position centered between the first pair of sides 108 of the electrode 107. In other embodiments, the fin 120 is not centered between the first pair of sides 108 of the
15 electrode 107.

The fin 120 is planar shape comprising a first face 191 and a second face 192. The first face 191 and the second face 192 of the fin 120 are substantially parallel to the first pair of sides 108 of the electrode 107. In other embodiments, the first
20 face 191 and the second face 192 of the fin 120 are positioned in orientations other than parallel to the first pair of sides 108 of the electrode 107.

The first face 191 and the second face 192 of the fin 120 extend from and substantially perpendicular to the top surface
25 110 of the electrode 107. In an alternative embodiment, the first face 191 and the second face 192 of the fin 120 extend from the top surface 110 of the electrode 107 at other than right angles.

5 The fin core 122 of the fin 120 is spot welded to the metallic mesh 114 comprising the electrode 107. In another embodiment, the fin 120 may be composed entirely of a polymeric material and attached to the electrode 107 by means known in the art.

10 FIG. 14(c) illustrates in detail a section of the lead 21 of this embodiment. The lead 21 comprises an electrically insulating sheath 141 and an electrical conductor 142.

15 The electrically insulating sheath 141 is disposed around the electrical conductor 142 (phantom view). The electrically insulating sheath 141 prevents the cardioversion/defibrillation energy passing through the electrical conductor 142 to the electrode from passing into objects surrounding the lead 21. The electrically insulating sheath 141, comprises a tube 149 disposed around the electrical conductor 142. The tube is composed of either silicone, polyurethane or composite materials. One skilled in the art will recognize that the tube 149 could alternately be composed of any insulating, flexible, bio-compatible material suitable to this purpose.

20 In this embodiment, the electrical conductor 142 comprises three highly-flexible, highly-conductive coiled fibers known as filars 147 (phantom view). These fibers are wound in a helical shape through the electrically insulating sheath 141. In an alternate embodiment, the filars lie as linear cables within the

5 electrically insulating sheath 141. In another alternate embodiment, a combination of helically coiled and linear filars lie within the electrically insulating sheath 141.

FIG. 14(d) illustrates a cross-section of a filar 147. The filars 147 of the embodiment illustrated comprise a metal core 144, a metal tube 143 and an insulating coating 140. The metal tube 143 is disposed around the metal core 144. The insulating coating 140 is disposed around the metal tube. The metal core 144 is made of silver and the metal tube 143 is made of MP35N[®] stainless steel, a product of SPS Technologies of Jenkintown, PA. The insulating coating 140 is made of teflon. The filars 147 of this structure are available as DFT[™] (drawn filled tube) conductor coil, available from Fort Wayne Metals Research Products Corp. of Fort Wayne, Indiana.

In an alternative embodiment, the filars 147 further comprise an intermediate coating (not shown) disposed between the metal tube 143 and the insulating coating 140. This intermediate coating is made of platinum, iridium ruthenium, palladium or an alloy of these metals.

In another alternative embodiment, the filars 147 comprise DBS[™] (drawn braised strands) also available from Fort Wayne Metals Research Products Corp. of Fort Wayne, Indiana.

Turning now to FIG. 14(e), a cross section of the lead fastener 146 is shown in detail. The lead fastener 146 provides

5 a robust physical and electrical connection between the lead 21 and the electrode 107.

10 In this embodiment, the lead fastener 146 comprises a metal strip 157, a crimping tube 154 and a crimping pin 156. The metal strip 157 has a first end 150, a second end 151, and a middle portion 152. The first end 150 and second end 151 of the metal strip 157 are separated by the middle portion 152. The first end 150 and second end 151 of the metal strip 157 are attached to the electrode 107. In this embodiment, the first end 150 and second end 151 of the lead fastener 146 are spot welded to the top surface 110 of the metallic mesh 114 comprising the electrode 107. In other embodiments, other fastening methods known in the art can be used.

15 The middle portion 152 of the metal strip 157 is raised away from the electrode 107 to permit the crimping tube 154 and electrically insulating sheath 141 of the lead 21 to fit between the metal strip 157 and the electrode 107.

20 The middle portion 152 of the metal strip 157 contains a crimp point 148. The crimp point 148 squeezes the crimping tube 154 and electrically insulating sheath 141 of the lead 21 thereby gripping it, and thereby providing a robust structural connection between the lead 21 and the electrode 107.

The filars 147 of the lead 21 are situated between the crimping tube 154 and crimping pin 156. The crimping tube 154

5 has a crimping point 155 which causes the filars 147 to be squeezed between crimping tube 154 and crimping pin 156. A gap 159 in the electrically insulating sheath 141 allows the crimping tube 155 to make contact the electrode 107, thereby forming a robust electrical connection.

10 The metal strip 157, the crimping tube 154 and crimping pin 156 are each made of platinum iridium. In an alternative embodiment, the metal strip 157, crimping tube 154 and crimping pin 156 are each made of a metal selected from the group consisting essentially of titanium, nickel alloys, stainless steel alloys, platinum, platinum iridium, and mixtures thereof.
15 In an alternative embodiment, the metal strip 157, crimping tube 154 and crimping pin 156 are each made of any conductive material.

FIG. 14(f) illustrates an exploded view of the lead fastener 146. In other embodiments, other types of lead fasteners 146 known in the art are used.
20

FIG. 15(a) illustrates an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the lead electrode assembly 100 illustrated in FIGS. 14(a)- 14(f). In this embodiment, however, the appendage 118 lacks a fin core 122. Moreover, as seen in FIG. 15(a) the lead electrode assembly 100 of this embodiment further comprises a backing layer 130 and stitching 139. The backing layer 130 acts
25

5 to insulate the electrode 107 so that cardioversion
/defibrillation energy may not pass to the tissue of the patient
that surrounds the top surface 110 of the electrode 107. This
has the effect of focusing the cardioversion/defibrillation
energy toward the heart of the patient through the bottom
10 surface 115 of the electrode 107.

The backing layer 130 comprises a base portion 158 and an
integrated fin 120. The base portion 158 of the backing layer
130 comprises a first surface 131, a second surface 132, a first
side 133 and a second side 134.

15 The base portion 158 of the backing layer 130 is attached
to the electrode 107 such that the second surface 132 of the
backing layer 130 lies directly adjacent to the top surface 110
of the electrode 107.

20 The base portion 158 of the backing layer 130 is formed so
that the first side 133 and the second side 134 are
substantially parallel and of substantially the same size as the
first pair of sides 108 of the electrode 107.

FIG. 15(b) illustrates a top view of the lead electrode
assembly 100 of this embodiment. The base portion 158 of the
25 backing layer 130 further comprises a distal end 137 and a
proximal end 138.

The distal end 137 and proximal end 138 of the backing
layer 130 are parallel to and of substantially the same size as

5 the second pair of sides 109 (hidden) of the electrode 107. The backing layer 130 contains a notch 136 on its distal end 137, through which the lead fastener 146 rises.

10 The base portion 158 of the backing layer 130 is attached to the electrode 107 with stitching 139. The stitching is composed of nylon. In alternate embodiments, the stitching is composed of any polymeric material.

15 The backing layer 130 is composed of polyurethane. In an alternative embodiment, the backing layer is composed of molded silicone, nylon, or Dacron®. In alternative embodiments, the backing layer is composed of any polymeric material.

20 The integrated fin 120 of the backing layer 130 is formed from the same piece of material as the backing layer 130. The integrated fin 120 has the same shape and dimensions as the fin 120 of the embodiment in FIG. 14.

25 In one embodiment, the integrated fin 120 is reinforced with a layer of Dacron® polymer mesh attached to the integrated fin 120. In another embodiment, the integrated fin 120 is reinforced with a layer of any polymeric material.

FIG. 16(a) illustrates an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the lead electrode assembly 100 illustrated in FIGS. 14(a)-14(e). In this embodiment, however, the fin 120 has a different construction.

5 Here, fin 120 comprises a first fin section 165, a second
fin section 160 and stitching 168. The first fin section 165 is
a rectangular sheet of polymeric material comprising an inside
face 167, an outside face 166, a first side 175 and a second
side 174. The first side 175 and second side 174 of the first
10 fin section 165 are substantially parallel and of substantially
the same size.

A line 173 divides the first fin section 165 into a first
half 171 and a second half 172. The line 173 runs parallel to
the first side 175 of the first fin section 165. The first half
15 171 of the first fin section 165 lies on one side of line 173.
The second half 172 of the first fin section 165 lies on the
other side of the line 173.

The second fin section 160 is a rectangular sheet of
polymeric material of the same size as the first fin section 165
20 comprising an inside face 162 and an outside face 161. The
second fin section 160 is divided in half substantially
similarly to the first fin section 165, thereby forming a first
half 163 and a second half 164 of the second fin section 160.

In an alternate embodiment, the first fin section 165 and
25 second fin section are not rectangular in shape. In an
alternate embodiment, the first fin section 165 and second fin
section have an oval shape.

5 The first half 171 of the first fin section 165 is fastened
to the first half 163 of the second fin section 160. The inside
face 167 of the first half 171 of the first fin section 165
faces the inside face 162 of the first half 163 of the second
fin section 160. The first fin section 165 is fastened the
10 second fin section 160 with stitching 168.

15 The fin 120 is attached to the top surface 110 of the
electrode 107. To accomplish this, the second half 172 of the
first fin section 165 is attached to the top surface 110 of the
electrode 107 with the stitching 169. The second half 164 of
the second fin section 160 is similarly attached to the top
surface 110 of the electrode 107 with stitching (not shown).

20 In one embodiment, the fin 120 is reinforced with a layer
of Dacron® polymer mesh positioned between the first fin section
165 and the second fin section 160 of the integrated fin 120. In
another embodiment, the Dacron® polymer mesh is attached only to
the first fin section 165 or the second fin section 160. In
other embodiments, the integrated fin 120 is reinforced with a
layer of any polymeric material attached to either or both fin
sections.

25 The appendage height of the fin 120 in this embodiment is
approximately 5 mm. In alternative embodiments, the appendage
heights range between approximately 1 mm and approximately 10
mm. The appendage length of the fin 120 in this embodiment is

5 approximately 1 cm. In alternative embodiments, appendage lengths range between approximately 2 mm and approximately 6 cm. In one embodiment, the appendage length of the fin 120 is such that the fin 120 is substantially as long as the electrode 107.

FIG. 17(a) illustrates a side plan view of an alternative
10 embodiment of the lead electrode assembly 100. The lead electrode assembly 100 comprises a connector 111, a lead 21, a lead fastener 146, an electrode 107, a backing layer 130 with an integrated fin tab 180, a molded cover 220 and an appendage 118.

15 The connector 111 is connected to the lead 21. The lead 21 is further connected to the electrode 107 with the lead fastener 146. The backing layer 130 is positioned over the electrode 107. The fin tab 180 protrudes from the backing layer 130. The molded cover 220 is disposed around the lead fastener 146 and the backing layer 130. The molded cover 220 is further
20 disposed around the fin tab 180 of the backing layer 118 to form the appendage 118. The molded cover 220 also partially envelops the electrode 107.

The connector 111 and the lead 21 are substantially similar to the connector 111 and the lead 21 described with reference to
25 FIGS. 14(a)-14(f). The lead comprises a distal end 101 and a proximal end 102. The distal end 101 of the lead 21 is attached to the connector 111. The proximal end 102 of the lead 21 is connected to the electrode 107 by the lead fastener 146.

5 In this embodiment, the lead fastener 146 comprises a first crimping tube 200, a crimping pin 202 and a second crimping tube 201. The first crimping tube 200 connects the proximal end 102 of the lead 21 to the crimping pin 202. The second crimping tube 201 connects the crimping pin 202 to the electrode 107.

10 The electrode 107 comprises a distal end 103 (phantom view), a proximal end 104, a top surface 110 and a bottom surface 115. The electrode further comprises three sections: a main body 217, a mandrel 219 and a mandrel neck 218.

15 The main body 217 of the electrode 107 is the region of the electrode 107 that makes contact with the tissue of the patient and transfers the cardioversion/defibrillation energy to the patient. This region is substantially rectangular, comprising a first pair of sides 108 (not shown) and a second pair of sides 109. The first pair of sides 108 of the electrode 107 are substantially parallel to each other. The second pair of sides 109 of the electrode 107 are also substantially parallel to each other. In another embodiment, the first pair of sides 108 and the second pair of sides 109 of the electrode 107 are non-parallel. The main body 217 of the electrode 107 is positioned
20
25 under the backing layer 130, so that the top surface 110 of the electrode faces the backing layer 130.

The mandrel 219 is a region of the electrode 107 shaped to facilitate the connection of the electrode 107 to the lead 21

5 via the lead fastener 146. The mandrel of the electrode is
crimped onto to the crimping pin 202 of the lead fastener 146
with the second crimping tube 201, so that a robust physical and
electrical connection is formed. The main body 217 of the
electrode 107 is connected to the mandrel 219 of the electrode
10 107 via the mandrel neck 218 of the electrode 107.

The backing layer 130 comprises a base portion 158 and an
integrated fin tab 180. The base portion 158 of the backing
layer 130 comprises a first surface 131, a second surface 132, a
distal end 137 and a proximal end 138.

15 The base portion 158 of the backing layer 130 is positioned
such that its second surface 132 is adjacent to the top surface
110 of the electrode 107. The base portion 158 of the backing
layer 130 is sized and positioned so that the distal end 137 and
proximal end 138 of the base portion 158 of the backing layer
20 130 overlay the second pair of sides 109 of the main body 217 of
the electrode 107. The distal end 137 and proximal end 138 of
the are also substantially parallel and of substantially the
same size as the second pair of sides 109 of the electrode 107.

25 The integrated fin tab 180 of the backing layer 130 is
formed from the same piece of material as the base portion 158
of the backing layer 130. The integrated fin tab 180 is formed
on the first surface 131 of the base portion 158 of the backing
layer 130.

5 The integrated fin tab 180 comprises a proximal edge 183, a distal edge 184, a top 185 and a bottom 186. The bottom 186 of the integrated fin tab 180 is joined to the first surface 131 of the base portion 158 of the backing layer 130. The proximal edge 183 and the distal edge 184 of the integrated fin tab 180 extend
10 from, and substantially perpendicular to the first surface 131 of the base portion 158 of the backing layer 130. The proximal edge 183 and distal edge 184 of the integrated fin tab 180 are parallel with each other. The integrated fin tab 180 is positioned so that its proximal edge 183 is substantially flush
15 with the proximal end 138 of the base portion 158 of the backing layer 130.

The backing layer 130 is composed of polyurethane. In an alternative embodiment, the backing layer 130 is composed of silicone. In another alternative embodiment, the backing layer
20 130 is composed of any polymeric material.

The molded cover 220 envelops and holds together the components of the lead electrode assembly 100. The molded cover 220 also provides rigidity to the lead electrode assembly 100. The molded cover 220 envelops the lead fastener 146 and the
25 backing layer 130. The fin 120 is formed when the molded cover 220 covers the fin tab 180. The thickness of the resulting fin 120 is approximately 2 mm. In alternate embodiments, the

5 thickness of the fin 120 is between approximately 1 mm and approximately 3 mm.

The appendage height of the fin 120 in this embodiment is approximately 5 mm. In alternative embodiments, the appendage heights range between approximately 1 mm and approximately 10 mm. The appendage length of the fin 120 in this embodiment is approximately 1 cm. In alternative embodiments, appendage lengths range between approximately 2 mm and approximately 6 cm. In one embodiment, the appendage length of the fin 120 is such that the fin is as long as the backing layer. In one embodiment, the appendage length of the fin 120 is such that the fin is as long as the electrode 107. In one embodiment, the appendage length of the fin 120 is such that the fin is as long as the molded cover 220.

The molded cover 220 also partially covers the bottom surface 115 of the electrode 107. In this way, the molded cover 220 attaches the backing layer 130 to the electrode 107.

The molded cover 220 in this embodiment is made of silicone. In an alternate embodiment, the molded cover 220 is made of any polymeric material. Stitching 360 holds the molded cover 220, the electrode 107 and the backing layer 130 together.

In one embodiment, the fin 120 is reinforced with a layer of Dacron® polymer mesh positioned between the molded cover 220 and the integrated fin tab 180. In another embodiment, the

5 Dacron® polymer mesh is attached only to the molded cover 220.
In other embodiments, the fin 120 is similarly reinforced with a
layer of any polymeric material.

As shown in FIG. 17(b), the fin 120 of the embodiment
illustrated in FIG. 17(a) can alternately have a sloped shape.
10 The sloped shape can reduce the resistance offered by the tissue
of the patient as it slides against the fin 120 during the
insertion of the lead electrode assembly 100 into the patient.
The slope-shaped fin 120 is constructed so that the proximal
edge 183 and distal edge 184 of the integrated fin tab 180 are
15 not parallel with each other. Instead, proximal edge 183 of the
integrated fin tab 180 can be curved so that the proximal edge
183 of the integrated fin tab 180 is closer to the proximal edge
184 at the top 185 of the integrated fin tab 180, than at the
bottom 186 of the integrated fin tab 180. In alternate
20 embodiments, the proximal edge 183 of the integrated fin tab 180
is not curved. Instead, the proximal edge 183 of the integrated
fin tab 180 is straight, and forms an acute angle with the first
surface 131 of the backing layer 130. In one alternate
embodiment, the proximal edge 183 of the integrated fin tab 180
25 forms a 45 degree angle with the first surface 131 of the
backing layer 130. In alternate embodiments, the distal edge
184 of the integrated fin tab 180 is curved. In alternate
embodiments, the distal edge 184 of the integrated fin tab 180

5 is straight and shaped so that it forms an acute angle with the first surface 131 of the backing layer 130.

FIG. 17(c) illustrates a front plan view of the lead electrode assembly 100 seen in FIG. 17(a). The base portion 158 of the backing layer 130 further comprises a first side 133 and
10 second side 134. The first side 133 and second side 134 of the base portion 158 of the backing layer 130 are substantially parallel. In an alternate embodiment, the first side 133 and second side 134 of the backing layer 130 are not parallel. The base portion 158 of the backing layer 130 is sized so that it is
15 substantially the same size and shape as the main body 217 of the electrode 107.

The integrated fin tab 180 of the backing layer 130 is planar, comprising a first face 181 and a second face 182. The first face 181 and second face 182 of the fin tab 180 are
20 substantially parallel with each other and with the first side 133 and second side 134 of the backing layer 130. The first face 181 and second face 182 of the fin tab 180 extend from, and substantially perpendicular to the first surface 131 of the backing layer 130. In another embodiment, the first face 181
25 and second face 182 of the fin tab 180 extend from the first surface 131 of the backing layer 130 at angles other than a right angle.

5 In an alternate embodiment, the first face 181 and a second face 182 of the integrated fin tab 180 of the backing layer 130 are not substantially parallel to each other. Instead, they are angled, such that they are closer together at the top 185 than they are at the bottom 186 of the integrated fin tab 180. This
10 shape can reduce the resistance offered by the tissue of the patient as it slides against the fin 120 during the insertion of the lead electrode assembly 100 into the patient.

15 In another embodiment, the first face 181 and a second face 182 of the integrated fin tab 180 of the backing layer 130 are angled, such that they are further apart at the top 185 than they are at the bottom 186 of the integrated fin tab 180. This shape can make the fin 120 easier to grip with a tool, such as a hemostat.

20 The fin tab 180 extends from the backing layer 130 at a position centered between the first side 133 and the second side 134 of the backing layer 130. In an alternate embodiment, the fin tab 180 is not centered between the first side 133 and the second side 134 of the backing layer 130.

25 An eyelet 301 is formed in the fin 120 of this embodiment. The eyelet can be used to facilitate the capture of the lead electrode assembly by a tool. The eyelet is formed as a hole
225 through the molded cover 220 and between the faces 181 and

5 182 of fin tab 180. In an alternate embodiment, no eyelet is formed in the fin 120.

The bottom surface 115 of the electrode 107 comprises a periphery 213 and a center 211. The molded cover 220 forms a skirt 222 around the periphery 213 of the bottom surface 115 of
10 the electrode 107. The skirt 222 of the molded cover 220 covers the periphery 213 of the bottom surface 115 of the electrode 107.

The skirt 222 of the molded cover 220 can act to focus cardioversion/defibrillation energy emitted from the electrode
15 107 of the lead electrode assembly 100 toward the heart of the patient. Because the thorax of a patient is surrounded by a layer of fat that is somewhat conductive, the cardioversion /defibrillation energy may tend to arc through this layer to reach the active surface 15 of the canister 11 (seen in FIG. 1)
20 without passing through the patient's heart. The skirt 222 of the lead electrode assembly 100 acts to minimize the loss of cardioversion /defibrillation energy to surrounding body tissues, or from being diverted away from the patient's heart.

The center 211 of the bottom surface 115 of the electrode
25 107 is not covered by the molded cover 220 and is left exposed. The width of the periphery 213 of the bottom surface 115 of the electrode 107 covered by the molded cover 220 is approximately .125 cm.

5 The area of the exposed center 211 of the bottom surface
115 of the electrode 107 is approximately 500 square mm. In
alternative embodiments, the length of the first pair of sides
108 and the second pair of sides 109 of the electrode 107 vary,
such that the area of the center 211 of the bottom surface 115
10 of the electrode has a surface area between approximately 100
sq. mm. and approximately 2000 sq. mm.

FIG. 17(d) illustrates an exploded top view of the lead
fastener 146 of the embodiments illustrated in FIGS. 17(a)-
17(c). The lead fastener connects the proximal end 102 of the
15 lead 21 and the distal end 103 of the electrode 107.

In this embodiment, the lead fastener 146 comprises a first
crimping tube 200, a crimping pin 202 and a second crimping tube
201. The crimping pin 202 comprises a first side 203 and a
second side 204.

20 The crimping tube 200 crimps the filars 147 of the lead 21
(here, only one representative filar 147 is shown) to the first
side 203 of crimping pin 202. The mandrel 219 of the electrode
107 is then wrapped around the second side 204 of the crimping
pin 202. Crimping tube 201 crimps the mandrel 219 to the second
25 side 204 of the crimping pin 202.

The first crimping tube 200, the second crimping tube 201
and the crimping pin 202 are each made of platinum iridium. In
an alternative embodiment, the first crimping tube 200, the

5 second crimping tube 201 and the crimping pin 202 are each made of a metal selected from the group consisting essentially of titanium, nickel alloys, stainless steel alloys, platinum, platinum iridium, and mixtures thereof. In other embodiments, the first crimping tube 200, the second crimping tube 201 and
10 the crimping pin 202 each comprise any conductive material.

The electrode 107 in this embodiment comprises a sheet of metallic mesh 206 prepared by the process described with reference to FIG. 14. The electrode 107 has a width measured parallel to the second pair of sides 109 of the electrode 107.
15 The width of the mandrel neck 218 of the electrode 107 is approximately 3 mm wide. The width of the mandrel of the electrode 107 is approximately 5 mm wide.

The first pair of sides 108 of the electrode 107 are approximately 5 cm in length. The second pair of sides 109 of the electrode 107 are approximately 1.9 cm in length. In
20 alternative embodiments, the length of the first pair of sides 108 and the second pair of sides 109 of the electrode 107 range independently from approximately 1 cm to approximately 5 cm.

The electrode 107 of this embodiment further comprises four
25 corners 112. The corners 112 of the electrode 107 are rounded. In an alternate embodiment, the corners 112 of the electrode 107 are not rounded.

5 FIGS. 17(e)-17(g) illustrate the size and position of the
fin 120 on the molded cover of the lead electrode assembly 100.

 FIGS. 18(a)-18(c) illustrate an alternative embodiment of
the lead electrode assembly 100. This embodiment is
substantially similar to the embodiments illustrated in FIGS.
10 17(a)-17(g). In this embodiment, however, the appendage height
of the fin 120 is approximately 1 cm. The appendage length of
the fin 120 in this embodiment is approximately 3.5 cm.

 As shown in FIG. 18(a), stitching 302 is placed through the
molded cover 220 and the fin 120 to prevent the molded cover 220
15 from sliding off the fin tab 180 when the molded cover 220 is
subjected to a force directed away from the electrode 107.

 As shown in FIG. 18(c), the fin 120 (phantom view) extends
approximately two thirds of the length of the electrode 107.

 FIG. 19 illustrates an alternative embodiment of the lead
20 electrode assembly 100. This embodiment is substantially
similar to the embodiments illustrated in FIGS. 17(a)-17(g). In
this embodiment, however, the backing layer 130 (not shown)
inside the molded cover 220 is curved. This results in an
electrode 107 that has a curvature of radius r , such that the
25 bottom surface 115 of the electrode 107 is concave.

 Because a curved electrode 107 may more closely approximate
the curvature of the patient's ribs, this curvature may have the
effect of making the lead electrode assembly 100 more

5 comfortable for the patient. In one embodiment, the radius r of
the curvature varies throughout the electrode 107 such that it
is intentionally shaped to approximate the shape of the ribs.
Lead electrode assemblies 100 can be custom manufactured with an
electrode 107 with a curvature r that matches the curvature of
10 the intended patient's ribcage in the vicinity of the ribcage
adjacent to which the electrode 107 is to be positioned.

In an alternative embodiment, lead electrode assemblies 100
are manufactured with an electrode 107 with a radius r that
matches the curvature of the ribcage of a statistically
15 significant number of people.

In another embodiment, lead electrode assemblies 100 with
electrodes 107 of varying curvatures can be manufactured to
allow an electrode radius r to be selected for implantation
based on the size of the patient. Smaller radii can be used for
20 children and for smaller adult patients. Larger radii can be
used for larger patients. The radius r of the curvature can
range from approximately 5 cm to approximately 35 cm depending
on the size of the patient.

In an alternative embodiment, the electrode 107 of the lead
25 electrode assembly 100 is flexible, such that it can be bent to
conform to the curvature of the intended patient's rib cage at
the time of implantation.

5 FIGS. 20(a)-20(c) illustrate an alternative embodiment of
the lead electrode assembly 100. This embodiment is
substantially similar to the embodiments illustrated in FIGS.
17(a)-17(g). In this embodiment, however, the backing layer 130
lacks an integrated fin tab 180 mounted on the first surface 131
10 of the backing layer 130. Moreover, this embodiment further
comprises a backing layer 400 having a fin tab 405.

FIGS. 20(a) and 20(b) illustrate only the backing layer
400, the fin tab 405 and the electrode 107 of this embodiment as
they are positioned relative to each other in the complete
15 embodiment. Other components of the embodiment are not shown.
FIG. 20(c) shows the embodiment in a complete form.

FIG. 20(a) illustrates a top plan view of the backing layer
400 and the electrode 107. The backing layer 400 is positioned
over the electrode 107. The electrode 107 of this embodiment is
20 substantially similar to the electrode 107 of the embodiment
illustrated in FIG. 17(d). In the complete embodiment, the
mandrel 219 of the electrode 107 is joined to the lead 21 (not
shown) by a lead fastener 146 (not shown) as shown in FIG.
17(a).

25 The backing layer 400 is a flat, planar member comprising a
distal end 137 and a proximal end 138. The backing layer 400
further comprises a first side 133, a second side 134, a first
surface 131, and a second surface 132 (not shown). The backing

5 layer 400 further comprises a width, W, measured as the distance between the first side 133 and the second side 134.

10 The backing layer 400 includes a fin tab 405 that is formed from the same piece of material as the backing layer 400. The first side 133 of the backing layer 400 lies over one of the first pair of sides 108 of the electrode 107 except over a fin tab region 407. In the fin tab region 407, the backing layer 400 is wider than the electrode 107. In the fin tab region 407, the first side 133 forms a fin tab 405 that protrudes from part of the first side 133 of the backing layer 400 outside the fin tab region 407. The fin tab 405 extends from the first side 133 of the backing layer 400 in an orientation substantially parallel to the top surface 110 of the electrode 107, beyond the first side 108 (phantom view) of the electrode 107.

15 20 The fin tab 405 comprises a first face 410 and a second face 411 (not shown). The first face 410 of the fin tab 405 is an extension of the first surface 131 of the backing layer 400. The second face 411 of the fin tab 405 is an extension of the second surface 132 of the backing layer 400.

25 Aside from the fin tab 405, the backing layer 405 is formed so that it is of substantially the same size and shape as the main body 217 of the electrode 107.

The backing layer 400, including the fin tab 405, is composed of polyurethane. In an alternate embodiments the

5 backing layer 400 and fin tab 405 are composed of any polymeric material.

FIG 20(b) is a side plan view of the backing layer 400 and the electrode 107. The backing layer 400 is positioned over the electrode 107 such that the second surface 132 of the backing
10 layer 400 is placed adjacent to the top surface 110 of the electrode 107.

FIG. 20(c) illustrates a bottom plan view of the complete embodiment, in which the backing layer 400 (not shown), the lead fastener 146 (not shown) and the fin tab 405 (phantom view) are
15 coated with a molded cover 220. When the molded cover 220 is applied over the backing layer 400, a fin 424 is formed over the fin tab 405 (phantom view). The fin 424 comprises a proximal end 404 and a distal end 403.

In one embodiment, the fin 424 is reinforced with a layer
20 of Dacron® polymer mesh positioned between the molded cover 220 and the fin tab 405. In another embodiment, the Dacron® polymer mesh is attached only to the molded cover 220. In other embodiments, the fin 424 is similarly reinforced with a layer of any polymeric material.

25 The appendage height, $h_{\text{Appendage}}$, of the fin 424 of this embodiment is approximately 5 mm. In alternative embodiments, the appendage heights range between approximately 1 mm and approximately 10 mm. The appendage length, $L_{\text{Appendage}}$, of the fin

5 424 of this embodiment is measured between the proximal end 404
and the distal end 403 of the fin 424. $L_{\text{Appendage}}$ is measured
where the fin 424 joins the rest of the lead electrode assembly
100. In this embodiment, the appendage length is approximately
1 cm. In alternative embodiments, the appendage lengths range
10 between approximately 2 mm and approximately 6 cm. In one
embodiment, the appendage length of the fin 424 is such that the
fin 424 runs the length of the electrode 107. In one
embodiment, the appendage length of the fin 424 is such that the
fin 424 runs the length of the backing layer 130 (not shown).
15 In one embodiment, the appendage length of the fin 424 is such
that the fin 424 runs the length of the molded cover 220.

FIG. 20(d) illustrates a bottom plan view of an alternate
embodiment of the lead electrode assembly 100. This embodiment
is substantially similar to the lead electrode assembly 100
illustrated in FIGS. 20(a)-20(c). In this embodiment, however,
20 proximal end 404 of the fin 424 is sloped. The slope shape of
the fin 424 is formed by the shape of the fin tab 405 (phantom
view) inside the fin 424. The backing layer 400 gradually
widens in the fin tab region 407 (not shown) with distance from
25 the proximal end 138 (not shown) to the distal end 137 (not
shown) of the backing layer 130 (not shown) until the appendage
height is reached. The proximal end 404 of the fin 424 is
straight and forms an acute angle with the first side 133 of the

5 base portion 158 of the backing layer 130 (not shown). In an alternate embodiment, the proximal end 404 of the fin 424 forms a 45 degree angle with the first side 133 of the base portion 158 of the backing layer 130 (not shown). In another embodiment, the proximal end 404 of the fin 424 is curved slope.

10 In alternate embodiments, the distal end 403 of the fin 424 is straight and shaped so that it forms an acute angle with the first side 133 of the base portion 158 of the backing layer 130 (not shown). In alternate embodiments, the distal end 403 of the fin 424 is curved.

15 FIGS. 21(a)-21(c) illustrate an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIGS. 15(a)-15(b). The integrated fin 120 is absent, however, from the backing layer 130.

20 The lead electrode assembly 100 of this embodiment further comprises a cylindrical rod 500 having a loop 515 formed therein. The loop 515 comprises the appendage 118 of this embodiment. The loop 515 is a member attached to the electrode 107 that can be gripped and used to precisely locate the
25 electrode 107 during its surgical implantation within the patient.

FIG. 21(a) illustrates a side plan view of the embodiment. The cylindrical rod 500 comprises a first straight portion 510,

5 a second straight portion 512 and a portion formed into a loop 515. The first straight portion 510 is separated from the second straight portion 512 by the loop 515.

The rod 500 is made of platinum iridium. In an alternative embodiment, the rod 500 is made of titanium or platinum.

10 The first straight portion 510 and second straight portion 512 are spot welded to the top surface 110 of the electrode 107. The loop 515 in the rod 500 extends away from the top surface 110 of the electrode 107.

15 The backing layer 130 is similar to the backing layer 130 illustrated in FIGS. 15(a)-15(b). The backing layer 130 is disposed over the electrode 107. The first straight portion 510 and second straight portion 512 of the rod 500 are positioned between the second surface 132 of the backing layer 130 and the top surface 110 of the electrode 107.

20 FIG. 21(b) illustrates a cross-sectional rear plan view of the embodiment of the lead electrode assembly shown in FIG. 21(a). The first straight portion 510 and second straight portion 512 are positioned such that they are parallel to the first pair of sides 108 of the electrode 107. The first
25 straight portion 510 and second straight portion 512 are both centered between the first pair of sides 108 of the electrode 107. In an alternative embodiment, the first straight portion 510 and second straight portion 512 are not parallel to and

5 centered between the first pair of sides 108 of the electrode
107.

FIG. 21(c) illustrates a top plan view of the embodiment of
the lead electrode assembly shown in FIG. 21(a). An aperture
517 is formed in the backing layer 130. The aperture 517 in the
10 backing layer is positioned such that the loop 515 extends
through and beyond the aperture 517 in a direction away from the
top surface 110 of the electrode 107. The backing layer 130 is
attached to the electrode 107 with stitching 139.

FIGS. 22(a)-22(d) illustrate an alternative embodiment of
15 the lead electrode assembly 100. This embodiment is
substantially similar to the embodiment illustrated in FIGS.
15(a)-15(b). This embodiment comprises a backing layer 610,
however, that lacks the integrated fin 120 illustrated in FIGS.
15(a)-15(b).

20 FIG. 22(a) illustrates a top plan view of the backing layer
610 of this embodiment prior to its attachment to the rest of
the lead electrode assembly 100. The backing layer 610 is cut
in a pattern as shown. The backing layer comprises a first
surface 131, a second surface 132 (not shown), a distal end 137,
25 a proximal end 138, a first side 133, a second side 134 and an
indented fin-forming region 620. The indented fin-forming
region 620 comprises a first edge 690 and a second edge 691.

5 The backing layer 610 is formed so that the first side 133 and the second side 134 are substantially parallel and of substantially the same size as the first pair of sides 108 of the electrode 107. The proximal end 138 is formed so that it is substantially perpendicular to the first side 133 and the second
10 side 134 of the backing layer 610. The proximal end 138 is longer than the second pair of sides 109 of the electrode 107 by a length A. The backing layer 610 has a varying width C measured from its distal end 137 to its proximal end 138 along a line parallel to its first side 133.

15 The backing layer is divided into three sections. A first backing section 693, a second backing section 692 and an indented fin-forming region 620 of length A. The length of the fin-forming region 620, A, is approximately 10 mm. In other
20 embodiments, the length of the fin-forming region 620, A, ranges between approximately 2 mm and approximately 20 mm.

 The area within the indented fin-forming region 620 is equally divided into a first fin area 612 and a second fin area 615. The dividing line 617 between the first fin area 612 and the second fin area 615 is substantially parallel to the first
25 side 133.

 The width, C, of the backing layer 610 is equal to the distance between the second pair of sides 109 of the electrode 107 except in the indented fin-forming region 620. In the

5 indented fin-forming region 620, the width, C, of the backing layer 610 is B. The width, B, of the backing layer 610 in the fin-forming region 620, is approximately 1 cm. In alternate embodiments, the width, B, of the backing layer 610 in the fin-forming region 620 ranges between approximately 2 mm and
10 approximately 6 cm. In other embodiments, however, the fin-forming region 620 ranges between 2 mm and the width, C, of the backing layer 610. In other embodiments, the fin-forming region 620 is longer than the width, C, of the backing layer 610.

15 The variation in width between the areas inside and outside the indented fin-forming region 620, forms the first edge 690 and a second edge 691 of the fin-forming region 620.

20 A first notch 136(a) is formed on the distal end 137 the first edge 690 of the fin-forming region 620 of the backing layer 130. A second notch 136(b) is formed on the distal end 137 the second edge 691 of the fin-forming region 620 of the backing layer 130.

25 The backing layer 610 in this embodiment is formed of flexible silicone. In alternative embodiments the backing layer 610 is formed of any bio-compatible, flexible polymeric material.

FIG. 22(b) illustrates a top plan view of the lead electrode assembly 100 of this embodiment. The backing layer 610 is attached to the electrode 107, so that the first edge 690

5 and a second edge 691 of the fin-forming region 620 of the backing layer 610 meet. This causes the backing layer 610 in the first fin area 612 and the second fin area 615 to fold together to form a fin 120.

10 The first notch 136(a) and second notch 136(b) formed on the distal end 137 the first edge 690 and second edge 691 of the fin-forming region 620 of the backing layer 130 meet to form a notch 136 on the distal end 137 of the backing layer, through which the lead fastener 146 rises. Stitching 660 holds the backing layer to the electrode 107.

15 FIG. 22(c) illustrates a side plan view of the lead electrode assembly 100 of this embodiment. Stitching 660 holds the first fin area 612 and a second fin area 615 of the backing layer 610 together to form the fin 120.

20 FIG. 22(d) illustrates a front plan view of the lead electrode assembly 100 of this embodiment. In one embodiment, the fin 120 is reinforced with a layer of Dacron® polymer mesh positioned between the first fin area 612 and a second fin area 615. In another embodiment, the Dacron® polymer mesh is attached only to either first fin area 612 or the second fin
25 area 615. In other embodiments, the fin 120 is similarly reinforced with a layer of any polymeric material.

FIGS. 22(e) and 22(f) illustrate an alternative embodiment of the lead electrode assembly 100. This embodiment is

5 substantially similar to the embodiment illustrated in FIGS.
22(a)-22(d). The backing layer 610 is substantially similar to
the backing layer 610 illustrated in FIG. 22(a). The backing
layer 610 in this embodiment, however, is cut along line 617.
The fin 120 of this embodiment comprises a proximal edge 129.
10 The proximal edge 129 of the fin 120 is slope-shaped. The
sloped shape can reduce the resistance offered by the tissue of
the patient as it slides against the fin 120 during the
insertion of the lead electrode assembly 100 into the patient.

FIGS. 23(a) and 23(b) illustrate a property of the
15 embodiment of the lead electrode assembly 100 illustrated in
FIGS. 22(e) and 22(f). The backing layer 610 is flexible, such
that the substantially planar fin 120 formed therefrom is
flexible and able to fold. Because the ability of the fin 120
to fold effectively reduces its appendage height, it may make
20 the fin more comfortable to the patient after it is implanted.

FIG. 23(a) shows fin 120 in an upright condition. When
pressure is applied perpendicular to the first surface 131 of
backing layer in the first fin area 612, along line 677 for
example, the fin 120 folds as shown in FIG. 23(b). When the fin
25 120 folds, its appendage height, $H_{\text{Appendage}}$, is reduced. This can
be seen by a comparison between FIG. 23(a) and FIG. 23(b).

The backing layer 610 in this embodiment is formed of a
polymeric material. In an alternative embodiment, the backing

5 layer 610 is formed of any bio-compatible, flexible polymeric material.

FIGS. 24(a)-24(c) illustrate an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIGS.
10 22(a)-22(d).

As shown in FIG. 24(a), however, the material from the first fin area 612 and the second fin area 615 of the backing layer 610 is not fastened together with stitching 660 in this embodiment. The resulting appendage 118 is formed in the shape of a tube.
15

In alternate embodiments, the backing layer 610 is coupled to the electrode 107 such that the material from the first fin area 612 and the second fin area 615 of the backing layer 610 does not touch except at the dividing line 617 between the first fin area 612 and the second fin area 615. The separation
20 between the first fin area 612 and the second fin area 615 of the backing layer 610 can allow the appendage 118 of this embodiment to be highly flexible. This flexibility can reduce the resistance offered by the tissue of the patient as it slides
25 against the appendage 118 during the insertion of the lead electrode assembly 100 into the patient.

FIG. 24(b) illustrates a side plan view of the embodiment illustrated in FIG. 24(a). The appendage 118 of this embodiment

5 comprises a proximal edge 129. The proximal edge 129 of the
appendage 118 is slope-shaped. The sloped shape can reduce the
resistance offered by the tissue of the patient as it slides
against the appendage 118 during the insertion of the lead
electrode assembly 100 into the patient.

10 In alternate embodiments, the proximal edge 129 of the tube
formed by the appendage 118 is closed. In one embodiment, the
proximal edge 129 of the appendage 118 is closed by a cap (not
shown). In another embodiment, the proximal edge 129 of the
appendage 118 is closed with stitching placed between the first
15 fin area 612 and the second fin area 615 only at the proximal
edge 129 of the appendage 118. In another embodiment, the
proximal edge 129 of the appendage 118 is closed by any other
means known in the art for this purpose.

20 FIG. 24(b) illustrates a top plan view of the embodiment
illustrated in FIGS. 24(a)-24(b).

FIGS. 25(a)-25(d) illustrate an alternative embodiment of
the lead electrode assembly 100. This embodiment is
substantially similar to the embodiment illustrated in FIGS.
15(a)-15(b). The backing layer 130 of this embodiment, however,
25 lacks an integrated fin 120.

FIG. 25(a) illustrates a front plan view of the lead
electrode assembly. The fin 120 in this embodiment comprises a
fin head 700 and flexible joining material 702.

5 The fin head 700 comprises a rectangular sheet having a first face 705, a second face 706, a first end 710 and a second end 712. The fin head 700 further comprises a height measured along the first face 705 between the first end 710 and the second end 712 and a length measured perpendicular to its height.

10 The fin head 700 is made of rigid silicone, which has a high durometer. In alternate embodiments, the fin head 700 is composed of any rigid bio-compatible material, such as a rigid bio-compatible polymeric material.

15 The flexible joining material 702 comprises a rectangular sheet having a first face 720, a second face 721, a first end 718 and a second end 719. The flexible joining material 702 further comprises a height measured along the first face between the first end 718 and the second end 719. The flexible joining material 702 also comprises a length measured perpendicular to its height. The length of the flexible joining material 702 is the same as the length of fin head 700.

20 The second end 712 of the second face 706 of the fin head 700 is attached to the first end 718 of the first face 720 of the flexible joining material 702. The fin head 700 is attached to the flexible joining material 702 with stitching 725. The second end 719 of the first face 720 of the flexible joining material 702 is attached to the first surface 131 of the backing

5 material 130. The flexible joining material 702 is attached to the backing material 130 with stitching 730.

The flexible joining material 702 is made of flexible silicone. It will be recognized by one skilled in the art, however, that the flexible joining material 702 may be made from
10 many other flexible materials, such as a flexible polymeric material.

FIG. 25(b) illustrates a property of the fin 120. When pressure is applied perpendicular to the first surface 705 of the fin head 205, the fin 120 folds as shown. When the fin 120
15 folds, its appendage height, $H_{\text{Appendage}}$, is reduced. This can be seen by a comparison between FIG. 25(a), which shows the fin 120 in an upright position and FIG. 25(b) which shows the fin 120 in a folded position.

FIG. 25(c) illustrates a top planar view of the lead
20 electrode assembly 100 of the embodiment illustrated in FIGS. 25(a) and 25(b). Neither the corners of the electrode 107 nor the corners 735 of the backing layer 130 of this embodiment are rounded. In an alternate embodiment, both the corners of the electrode 107 and the corners 735 of the backing layer 130 of
25 this embodiment are rounded.

FIG. 26 illustrates an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIGS. 25(a)-25(d). The

5 backing layer 130 of this embodiment, however, lacks a fin head 700 and flexible joining material 702.

Moreover, the appendage 118 in this embodiment comprises a tube 740 having an interior 755, an exterior 756, a proximal end 757 and a distal end 758. The tube comprises a sheet of
10 material 750. The sheet of material 750 is substantially rectangular having a first pair of sides 751, a second pair of sides 752, a first surface 753 and a second surface 754.

The sheet of material 750 is folded so that its first pair of sides 751 abut each other. The folded sheet of material 750
15 forms a tube 740. The first surface 753 of the sheet of material 750 faces the interior 755 of the tube 740. The second surface 754 of the sheet of material 750 faces the exterior of the tube 756. In folding the sheet of material 750 so that the first pair of sides 751 abut each other, the second pair of
20 sides 752 of the sheet of material 750 are folded in a circular shape to form the proximal end 757 and distal end 758 of the tube 740. This results in the tube 740 having a cylindrical shape. The diameter of the circular proximal end 757 and distal end 758 of the tube 756 is approximately 5 mm. In alternate
25 embodiments, the diameter range between approximately 1 mm and approximately 10 mm. The length of the tube 756 as measured between the proximal end 757 and distal end 758 of the tube 756 is approximately 1 cm. In alternate embodiments, length of the

5 tube 756 ranges between approximately 2 mm and approximately 6 cm. In one embodiment, the tube 756 is substantially as long as the electrode 107.

The second surface 754 of the sheet of material 750 is attached to the first surface 131 of the backing layer 130. The
10 first pair of sides 751 of the sheet of material 750 are attached to the backing layer 130 with stitching 760.

In alternate embodiments, the proximal end 757 of the tube 740 is closed. In one embodiment, the proximal end 757 of the tube 740 is closed by a cap (not shown). In another embodiment,
15 the proximal end 757 of the tube 740 is closed by holding one of the second pair of sides 752 of the sheet of material 750 closed with stitching. In another embodiment, the proximal end 757 of the tube 740 is closed by any other means known in the art for this purpose.

20 It should be noted that the appendage 118 in some alternative embodiments comprises a tube with a shape other than a cylinder. An example of a tube with a shape other than cylindrical is illustrated below in FIG. 27.

FIG. 27 illustrates an alternative embodiment of the lead
25 electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIG. 26. The tube 740 comprising a sheet of material 750, however, is absent from this embodiment.

5 Moreover, the appendage 118 of this embodiment comprises a
tube 770 having an interior 755 an exterior 756, a proximal end
757 and a distal end 758. The tube comprises a first sheet of
material 775, a second sheet of material 776 and a third sheet
of material 777. The first sheet of material 775, the second
10 sheet of material 776 and the third sheet of material 777 are
all substantially rectangular in shape. Each comprises a first
pair of sides 784, a second pair of sides 786, a first surface
788 and a second surface 789. The first pair of sides 784 of
each sheet of material are parallel to each other. In another
15 embodiment, the first pair of sides 784 of each sheet of
material are non-parallel. The second pair of sides 786 of each
sheet of material are parallel to each other. In another
embodiment, the second pair of sides 786 of each sheet of
material are non-parallel.

20 The first pairs of sides 784 of each sheet of material are
attached to the first pair of sides 784 of the other sheets of
material. In this way the second pair of sides 786 of the first
sheet of material 775, the second sheet of material 776 and the
third sheet of material 777 form a triangular shaped proximal
25 end 757 and distal end 758 of the tube 770. The sheets of
material are attached to each other such that the second surface
789 of each sheet of material faces the interior 755 of the tube

5 770. The sheets of material are attached to each other with stitching 791.

The height of the tube 770 is approximately 5 mm. In alternate embodiments, the height ranges between approximately 1 mm and approximately 10 mm. The length of the tube 770 as measured between the proximal end 757 and distal end 758 of the tube 770 is approximately 1 cm. In alternate embodiments, length of the tube 770 ranges between approximately 2 mm and approximately 6 cm. In one embodiment, the tube 770 is substantially as long as the electrode 107.

15 The second sheet of material 776 is attached to the backing layer 130 with stitching 790. The first surface 788 of the second sheet of material 776 is positioned next to the first surface 131 of the backing layer 130.

In alternate embodiments, some or all of the sheets of material are reinforced with a layer of Dacron® polymer mesh. In one embodiment, the Dacron® polymer mesh is attached to the first surface 788 of each sheet of material. In another embodiment, the Dacron® polymer mesh is attached to the second surface 789 of each sheet of material. In another embodiment, the sheets of material are similarly reinforced with a layer of any polymeric material.

In alternate embodiments, the proximal end 757 of the tube 770 is closed. In one embodiment, the proximal end 757 of the

5 tube 770 is closed by a cap. In another embodiment, the proximal end 757 of the tube 770 is closed by holding the sides 786 of the first sheet of material 775, the second sheet of material 776 and the third sheet of material 777 that form the proximal end 757 of the tube 770 together with stitching. In
10 another embodiment, the proximal end 757 of the tube 770 is closed by any other means known in the art for this purpose.

FIGS. 28(a)-28(d) illustrate various possible positions for the appendage 118 relative to the lead 21 of the lead electrode assembly 100. Additionally, up to this point, all embodiments of the electrode 107 illustrated and discussed have had a rectangular shape. These figures illustrate alternative
15 embodiments with electrodes 107 of different shapes.

At this point, it is useful to set out two definitions in order to discuss the possible orientation of appendages 118.

20 The interface line is defined as the center line of the appendage 118 as traced on the electrode 107. FIG. 28(a) illustrates the interface line 800 of the appendage 118 of a lead electrode assembly 100.

The line of the lead is defined as the line along which the
25 lead 21 of the lead electrode assembly 100 enters the lead fastener 146. The line of the lead 805 of line 21 is shown as it enters the lead fastener 146 (in phantom). As the lead 21 approaches the lead fastener 146, the closest section 807 of the

5 lead 21 forms the line of the lead. When the lead 21 is not bent, the entire lead 21 lies along the line of the lead.

FIG. 28(b) illustrates an embodiment wherein the lead 21 is not bent and the entire lead 21 lies along the line of the lead 805.

10 The electrode length, $L_{\text{Electrode}}$, is the length of the electrode 107 as measured along the interface line 800.

15 In the embodiments of the lead electrode assembly 100 shown in FIGS. 28(b) and 28(c), the interface line 800 is the same line as the line of the lead 805. In the embodiment shown in FIG. 28(a) the interface line 800 is parallel with the line of the lead 805.

In the embodiment of the lead electrode assembly 100 shown in FIG. 28(d), the interface line 800 intersects the lead fastener 146 (phantom view).

20 FIGS. 28(e)-28(h) show various additional electrode shapes disposed in various lead electrode assemblies 100. The electrode shapes are not limited, however, to the shapes specifically illustrated.

25 The electrode 204 depicted in FIG. 28(e) has a "thumbnail" shape. The proximal end 104 of this electrode 107 is generally rounded. As the electrode 107 moves distally along its length, the conductive surface terminates at the distal end 103 of the electrode 107.

5 An ellipsoidal shaped electrode 107 is depicted in FIG.
28(f). The proximal end 104 of the ellipsoidal shaped electrode
107 is generally rounded. As the ellipsoidal shaped electrode
107 moves distally along its length, the conductive surface
terminates in a rounded distal end 103.

10 A circular shaped electrode 107 is illustrated in FIG.
28(g).

15 A triangular shaped electrode 107 is depicted in FIG.
28(h). Triangular shaped electrodes 107 also incorporate
electrodes that are substantially triangular in shape. In
particular to FIG. 28(h), the corners of the triangular shaped
electrode 107 are rounded.

Several lead electrode assembly manipulation tools 927 have
been developed to manipulate the lead electrode assemblies
during their surgical implantation.

20 FIG. 29 illustrates an embodiment of a lead electrode
assembly manipulation tool 927. The lead electrode assembly
manipulation tool 927 comprises an enhanced hemostat 930 used to
manipulate lead electrode assemblies 100 comprising an eyelet
during their implantation in patients.

25 The enhanced hemostat 930 comprises the following
components: a hemostat having a first prong 931, a second prong
932, a hinge 939 and an eyelet pin 940. The first prong 931 is

5 attached to the second prong 932 by the hinge 939. The eyelet pin is attached to the second prong 932.

The first prong 931 comprises a first end 933 and a second end 934. The second prong 932 comprises a first end 935 and a second end 936. The first prong and second prong are
10 approximately 75 cm long and curved with a radius of approximately 30 cm. In alternate embodiments, the curvature of the hemostat does not have a radius of approximately 30 cm, but instead approximates the curvature of the thorax of a patient. In one embodiment, the curvature of the hemostat approximates
15 the curvature of the thorax of a patient along a subcutaneous path taken from the anterior axillary line, posteriorly toward the spine.

The first prong 931 is pivotally attached to the second prong 932 by the hinge 939. The hinge is attached to the first prong 931 approximately 10 cm from the first end 933. In this
20 embodiment, the hinge is attached to the second prong 932 approximately 10 cm from the second end 935.

The eyelet pin 940 can be inserted through the eyelet 301 of a fin 120 of the lead electrode assembly 100 such as the lead
25 electrode assembly 100 discussed with reference to FIG. 17(a)-17(g) as a means of capturing the lead electrode assembly 100 prior to its implantation in a patient.

5 The eyelet pin 940 is a cylindrical member having a first
end 941 and a second end 942. In an alternate embodiment, the
eyelet pin 940 is a hook-shaped member. The diameter of the
cylinder is approximately 2 mm. In alternate embodiments, the
diameter of the cylinder ranges from approximately 1 mm to
10 approximately 5 mm. The length of the eyelet pin 940 is
approximately 8 mm. In alternate embodiments, the length of the
eyelet pin 940 ranges from approximately 4 to approximately 15
mm.

15 The first end of the eyelet pin 940 is attached to the
second prong 932, approximately 8 mm from the second end 936 of
the second prong 932. In alternate embodiments, the eyelet pin
940 is attached to the second prong 932 at various lengths from
the second end 936 of the second prong 932.

20 The eyelet pin 940 is attached to the second prong 932 in
an orientation perpendicular to the length of the second prong
932. The eyelet pin 940 is attached to the second prong 932 so
that it extends away from the second end 934 of the first prong
931.

25 In this embodiment, all of the components are made of
stainless steel. In an alternative embodiment, some or all of
the components are composed metals other than stainless steel or
are composed of a polymeric material.

5 We now turn to a discussion of the positions of the components that comprise an entire S-ICD system including the lead electrode assembly 100 when it is implanted in a patient.

FIGS. 30(a) and 30(b) illustrate an embodiment of the S-ICD system implanted in a patient as a means of providing
10 cardioversion/defibrillation energy.

FIG. 30(a) is a perspective view of a patient's ribcage with an implanted S-ICD system. The S-ICD canister 11 is implanted subcutaneously in the anterior thorax outside the ribcage 1031 of the patient, left of the sternum 920 in the area
15 over the fifth rib 1038 and sixth rib 1036. The S-ICD canister 11, however, may alternately be implanted anywhere over the area between the third rib and the twelfth rib. The lead 21 of the lead electrode assembly 100 is physically connected to the S-ICD canister 11 where the transthoracic cardiac pacing energy or
20 effective cardioversion/defibrillation shock energy (effective energy) is generated. The term "effective energy" as used in this specification can encompass various terms such as field strength, current density and voltage gradient.

The lead 21 of the lead electrode assembly 100 travels from
25 the S-ICD canister 11 to the electrode 107, which is implanted subcutaneously in the posterior thorax outside the ribcage 1031 of the patient in the area over the eighth rib 1030 and ninth rib 1034. The electrode 107, may alternately be implanted

5 subcutaneously anywhere in the posterior thorax outside the
ribcage 1031 of the patient in the area over the third rib 1030
and the twelfth rib 1034. The bottom surface 115 of the
electrode 107 faces the ribcage. The electrode or active
surface 15 (phantom view) of the canister 11 also faces the
10 ribcage.

FIG. 30(b) is a cross-sectional side plan view of the
patient's rib cage. Here it is seen that the lead 21 travels
around the circumference of the thorax, in the subcutaneous
layer beneath the fat 1050 between the outside of the ribcage
1031 and the skin 1055 covering the thorax.

We now turn to a discussion of a method by which the lead
electrode assembly 100 of the S-ICD system is implanted in a
patient using a standard hemostat as well as the enhanced
hemostat described above. FIG. 31 and FIGS. 32(a)-32(d)
20 illustrate aspects of this method.

In operation, as seen in FIG. 31, an incision 905 is made
in the patient 900 in the anterior thorax between the patient's
third and fifth rib, left of the sternum 920. The incision can
alternately be made in any location between the patient's third
25 and twelfth rib. The incision can be made vertically (as
shown), horizontally or angulated. In order to minimize
scarring, the incision can be made along Langher's lines.

5 FIG. 32(a) shows a bottom view cross-section of the patient
900, along the line 32(a) shown in FIG. 31. A hemostat 930,
with prongs 932 is introduced into the incision 905. The
hemostat 930 is inserted with its prongs together without
anything gripped between them. The prongs 932 of the hemostat
10 930 are pushed through the fat 1050 between the skin 1055 of the
thorax and the ribcage 1031 to create a subcutaneous path 1090.
The prongs 932 of the hemostat 930 can alternately be pushed
beneath the fat 1050 that lies between the skin 1055 of the
thorax and the ribcage 1031 to create a subcutaneous path 1090
15 between the fat 1050 and the ribcage 1031.

20 The hemostat is moved around the ribcage 1031 until the
subcutaneous path 1090 reaches within approximately 10 cm of the
spine 1035 between the eighth rib 1030 and ninth rib 1034 (this
location is best seen in FIG. 30(a)) between the skin 1055 and
the ribcage 1031. The subcutaneous path 1090 can alternately be
made to reach any location between the skin 1055 and the ribcage
1031 between the patient's third and twelfth rib. The hemostat
930 is then withdrawn. Alternately, the hemostat 930 can be
moved around the ribcage 1031 until the subcutaneous path 1090
25 terminates at a termination point 1085 at which a line 1084
drawn from the termination point 1085 to the incision 905 would
intersect the heart 910.

5 Next, as shown in FIG. 32(b), the appendage 118 of a lead electrode assembly 100, is squeezed between the tongs 932 of a hemostat 930.

As shown in FIG. 32(c), the lead electrode assembly 100 and hemostat tongs 932 are introduced to the subcutaneous path 1090 and pushed through the subcutaneous path until the lead electrode assembly 100 reaches the termination point 1085 of the path. The appendage 118 of the lead electrode assembly 100 is then released from the tongs 932 of the hemostat 930. The hemostat 930 is then withdrawn from the subcutaneous path 1090.

15 In an alternative method, the enhanced hemostat 930 seen in FIG. 29 is used to introduce the lead electrode assembly 100 into the subcutaneous path 1090 created as discussed above. After the subcutaneous path 1090 is created, the lead electrode assembly 100 is attached to the enhanced hemostat 930 as shown in FIG. 32(d). Eyelet pin 1108 is inserted through the eyelet 301 in the fin 120 of the lead electrode assembly 100. The enhanced hemostat 930 is then used to introduce the lead electrode assembly 100 into the subcutaneous path 1090, as shown in FIG. 32(c). The lead electrode assembly 100 is then moved through the subcutaneous path 1090 until the electrode 107 reaches the end of the path 1085. The enhanced hemostat 930 is then moved until the lead electrode assembly 100 is released

5 from the eyelet pin 940. The enhanced hemostat 930 is then withdrawn from the subcutaneous path 1090.

FIGS. 33(a)-33(c) illustrate an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiments illustrated in FIGS. 10 17(a)-17(g). The backing layer 130 of this embodiment, however, lacks an integrated fin tab 180. Moreover, the appendage 118 of the lead electrode assembly 100 of this embodiment comprises a rail 1100.

FIG. 33(a) illustrates the rail 1100 of the lead electrode assembly 100 of this embodiment. The rail 1100 is a member 15 attached to the electrode 107 that can be captured by a lead electrode assembly manipulation tool and used to precisely locate the electrode 107 during its surgical implantation within the patient. The rail 1100 comprises three sections: a foundation 1105, a riser 1110 and a head 1115. The foundation 20 1105 is separated from the head 1115 by the riser 1125.

The foundation 1105 comprises a flat, substantially planar member, comprising a first pair of sides 1106 and a second pair of sides 1107. The first pair of sides 1106 of the foundation 25 1105 are substantially linear and substantially parallel. In an alternate embodiment, the first pair of sides 1106 of the foundation 1105 are neither linear nor parallel. The length of the first pair of sides 1106 of the foundation 1105 is

25

The foundation 1105 further comprises a top surface 1120 and a bottom surface 1121. The foundation 1105 has a thickness, measured as the distance between the top surface 1120 and the bottom surface 1121. The thickness of the foundation 1105 is 2 mm. In alternate embodiments, the thickness of the foundation 1105 ranges between approximately 1 mm and approximately 5 mm.

100

5 a proximal end 1123 and a distal end 1124. The first face 1125
and second face 1126 are parallel to each other and
perpendicular to the top surface 1120 of the foundation 1105.
The first face 1125 and a second face 1126 of the riser 1110 are
parallel to the first pair of sides 1106 of the foundation 1105.
10 The bottom 1128 of the riser 1110 joins the foundation 1105 in a
position centered between the first pair of sides 1106 of the
foundation 1105. The proximal end 1123 of the riser 1110 and
the distal end 1124 of the riser 1110 are parallel to each other
and perpendicular to the top surface 1120 of the foundation
1105. In other embodiments, the proximal end 1123 of the riser
1110 and the distal end 1124 of the riser 1110 are not parallel
to each other.

In one embodiment, the proximal end 1123 of the riser 1110
is not perpendicular the top surface 1120 of the foundation
1105. Instead, the proximal end 1123 of the riser 1110 is
sloped, so that the proximal end 1123 and the distal end 1124 of
the riser 1110 are closer at the top 1127 of the riser 1110 than
at the bottom 1128 of the riser. A slanted proximal end 1123
make the rail 1100 of the lead electrode assembly 100 offer less
25 resistance against the tissues of the patient during insertion
into the patient.

The height of the riser, H_{riser} , is measured as the distance
between the top surface 1120 of the foundation 1105 to the head

5 1115, perpendicular to the top surface 1120 of the foundation 1105. The height of the riser is approximately 5 mm. In alternate embodiments, the height of the riser ranges from approximately 1 mm to approximately 10 mm.

10 The riser 1110 has a width, measured as the distance between the first face 1125 and the second face 1126. The width of the riser 1110 is 2 mm. In alternate embodiments, the width of the riser 1110 ranges from approximately 1 mm to approximately 6 mm.

15 Turning now to the head 1115, the head 1115 is a flat, substantially planar member. The head 1115 comprises a first pair of sides 1136, a second pair of sides 1137, a top surface 1116 and a bottom surface 1117 (not shown). The first pair of sides 1136 and the second pair of sides 1137 of the head 1115 are substantially linear and substantially parallel. In an alternate embodiment, the first pair of sides 1136 of the head 1115 are neither linear nor parallel. In an alternate embodiment, the second pair of sides 1137 of the head 1115 are neither linear nor parallel.

20 The length of the first pair of sides 1136 of the head 1115 is equal to the length of the first pair of sides 1106 of the foundation 1105. In alternate embodiments, the length of the first pair of sides 1136 of the head 1115 is unequal to the length of the first pair of sides 1106 of the foundation 1105.

5 The length of the second pair of sides 1137 of the head 1115 is approximately 5 mm. In alternate embodiments, the length of the second pair of sides 1137 of the head 1115 ranges from approximately 3 mm to approximately 10 mm.

10 The bottom surface 1117 of the head 1115 joins the top 1127 of the riser 1110 opposite the foundation 1105 of the rail 1100. The top surface 1116 and the bottom surface 1117 of the head 1115 are parallel to the top surface 1120 of the foundation 1105. In an alternate embodiment, the top surface 1116 and the bottom surface 1117 of the head 1115 are not parallel to the top surface 1120 of the foundation 1105.

15 The head 1115 has a thickness, measured as the distance between the top surface 1116 and the bottom surface 1117 of the head 1115. The thickness of the head 1115 is approximately 2 mm. In alternate embodiments, the thickness of the head ranges between approximately 2 mm and approximately 10 mm.

20 The foundation 1105, the head 1115 and the riser 1110 are made of stainless steel. In alternate embodiments, some or all of the sections of the rail 1100 are made of metals other than stainless steel. In alternate embodiments, some or all of the sections of the rail 1100 are made of a polymeric material wherein the polymeric material is selected from the group consisting essentially of a polyurethane, a polyamide, a

5 polyetheretherketone (PEEK), a polyether block amide (PEBA), a
polytetrafluoroethylene (PTFE), a silicone and mixtures thereof.

The foundation 1105, the head 1115 and the riser 1110 are
machined from the same piece of material. In an alternate
embodiment, some or all of the sections are formed independently
10 and welded to the others.

Turning in detail to FIG. 33(b), the position of the rail
1100 within the lead electrode assembly 100 will be discussed.
The rail 1100 is positioned so that its bottom surface 1121 is
adjacent to and covers a region of the first surface 131 of the
backing layer 130. The rail is centered between the first side
15 133 and second side 134 of the backing layer 130. In an
alternate embodiment, the rail is not centered between the first
side 133 and second side 134 of the backing layer 130.

In an alternate embodiment, there is no backing layer 130
20 and the rail 1100 is positioned so that its bottom surface 1121
is adjacent to the top surface 110 of the electrode 107.

Turning now to the electrode 107 of this embodiment, the
electrode 107 is the same shape and size as the electrode 107
discussed with reference to FIGS. 17(a)-(g). In alternative
25 embodiments, the length of the first pair of sides 108 (not
shown) and second pair of sides 109 (not shown) of the electrode
107 range independently between approximately 1 cm and
approximately 5 cm.

5 Turning now to the molded cover 220, the skirt 222 of the
molded cover 220 partially covers the bottom surface 115 of the
electrode 107 as discussed with reference to FIG. 17(d). The
molded cover 220 further substantially covers the first surface
131 of the backing layer 130. The molded cover 220 does not
10 cover the first surface 131 of the backing layer 220 in the
region in which the bottom surface 1121 of the rail 1100 is
adjacent to the backing layer 130. Instead, the molded cover
220 in this region substantially covers the top surface 1120 of
the rail 1100. The molded cover 220 abuts the first face 1125
15 and second face 1126 of the riser 1110 of the rail 1100.

Turning to FIG. 33(c), the position of the lead 21 and the
appendage 118 will now be discussed. The interface line 800 of
the appendage 118 and the line of the lead 805 are the same
line. In an alternate embodiment, interface line 800 of the
20 appendage 118 and the line of the lead 805 are not the same
line. The line of the lead 805 is centered between the first
pair of sides 108 (phantom view) of the electrode 107 (phantom
view). In an alternate embodiment, the line of the lead 805 is
not centered between the first pair of sides 108 of the
25 electrode 107.

FIG. 34 illustrates an alternative embodiment of the lead
electrode assembly 100. This embodiment is substantially
similar to the embodiment illustrated in FIGS. 33(a)-33(c). In

5 this embodiment, however, the dimensions of the electrode 107 are different from those of the embodiment illustrated in FIGS. 33(a)-33(c).

The first pair of sides 108 of the electrode 107 (phantom view) are approximately 2.4 cm in length. The second pair of
10 sides 109 of the electrode 107 are approximately 4 cm in length. In alternative embodiments, the length of the first pair of sides 108 and second pair of sides 109 of the electrode 107 range independently between approximately 1 cm and approximately 5 cm.

15 The interface line 800 of the rail 1100 is parallel to the line of the lead 805. In an alternate embodiment, the interface line 800 of the rail 1110 is not parallel to the line of the lead 805. The interface line 800 of the rail 1100 is centered between the first pair of sides 108 of the electrode 107. In an
20 alternate embodiment, the interface line 800 of the rail 1100 is not centered between the first pair of sides 108 of the electrode 107.

The line of the lead 805 is not centered between the first pair of sides 108 of the electrode 107. Because the lead 805 is
25 not centered between the first pair of sides 108 of the electrode 107, the lead rail 1110 may be more easily accessed by a lead electrode manipulation tool (not shown). In an alternate

5 embodiment, the line of the lead 805 is centered between the first pair of sides 108 of the electrode 107.

FIG. 35 illustrates a lead electrode assembly manipulation tool 927 useful for manipulating a lead electrode assembly (not shown) having an appendage 118 comprising a rail 1100 during the
10 implantation of the lead electrode assembly 100 in a patient. Examples of such lead electrode assembly 100 embodiments are shown in FIGS. 33(a)-33(c) and 34.

The lead electrode assembly manipulation tool 927 comprises a handle 1142, a rod 1144 and a rail fork 1146. The handle 1142
15 is connected to the rod 1144. The rail fork 1146 is also connected to the rod 1144.

The rod 1144 is a cylindrical member with a diameter of approximately 4 mm, approximately 25 cm in length, having a proximal end 1147 and a distal end 1148. The rod 1144 is curved
20 with a radius of approximately 20 cm.

The rod is made of steel. In other embodiments, the rod is composed of titanium, a polymeric material or any other material suitable for this purpose.

The handle 1142 is a cylindrical member with a diameter
25 sized to fit comfortably in the palm of a surgeon's hand. The rod is connected to the proximal end 1147 of the rod 1144. In an alternate embodiment, the handle 1142 is not cylindrical. In

5 an alternate embodiment, the handle 1142 has ergonomic contours.

The handle is made of polyurethane. In an alternate embodiment, the handle is made of any metal, or any polymeric material suitable for this purpose.

10 Turning now to FIG. 35(b), the rail fork 1146 is attached to the distal end 1148 of the rod 1144. The rod further comprises a slot 1162 in its distal end. The rail fork comprises a pair of tines 1151 separated by a gap 1153 and a tine base 1160 having a tang 1161.

15 Each of the pair of tines 1151 has a proximal end 1154 and a distal end 1155. The proximal ends 1154 of the pair of tines 1151 are attached to the tine base 1160. Each of the pair of tines 1151 has a substantially rectangular form with straight inner sides 1156 and straight outer sides 1157. The distal ends 20 1155 of each of the pair of tines 1151 are rounded. The length of the pair of tines 1151, measured from the distal end 1155 to the proximal end 1154, is substantially equal to the length of the first pair of sides 1106 of the rail 1100 of the lead electrode assembly 100. In alternate embodiments, the length of 25 the pair of tines 1151 is substantially greater than or less than the length of the first pair of sides 1106 of the rail 1100.

5 The pair of tines 1151 are separated by a gap 1153 formed
by the inner sides 1156 of the pair of tines 1151 and the tine
base 1160.

10 The pair of tines 1151 and the tine base 1160 comprising
the rail fork 1146 are punched from a single sheet of steel
having a thickness of approximately 3 mm. In other embodiments,
the rail fork 1146 is composed of titanium, a polymeric material
or any other material suitable for this purpose. In one
embodiment, the handle 1142, the rod 1144 and the rail fork 1146
are all made from the same piece of material.

15 FIG. 35(c) illustrates a side plan view of the lead
electrode assembly manipulation tool 927. The rod 1144 further
comprises a slot 1162 in its distal end 1148. The tine base
1160 connects the pair of tines 1151 to the distal end 1148 of
the rod 1144. The tine base 1160 comprises a tang 1161 (phantom
20 view). The tang 1161 is inserted in the slot 1162 in the rod
1144. The tang 1161 is welded in the slot 1162 of the rod 1144.

We now turn to a description of the use of the lead
electrode assembly manipulation tool 927 in the implantation of
a lead electrode assembly 100 into a patient.

25 As discussed with reference to FIG. 31, an incision 905 is
made in the patient 900. As discussed with reference to FIG.
32(a), a subcutaneous path 1090 is created in the patient 900
with a hemostat 932.

5 As shown in FIG. 35(d), the lead electrode assembly 100 is then captured by the lead electrode assembly manipulation tool 927. The rail 1110 of the lead electrode assembly 100 is inserted into the rail fork 1146 of the lead electrode assembly manipulation tool 927. The riser 1110 (phantom view) of the
10 rail is placed into the gap 1153 between the pair of tines 1151 of the rail fork 1146. The pair of tines 1151 fit between the bottom surface 1117 of the head 1115 of the rail 1100 and the molded cover 220. The rail 1100 is slid toward the proximal end 1155 of the pair of tines 1151 until the riser 1110 of the rail
15 1100 reaches the tine base 1160 of the rail fork 1146. The lead 21 of the lead electrode assembly 100 can then be pulled in toward the handle 1142 of the lead electrode assembly manipulation tool 927 until it is taught. This acts to prevent the rail 1100 of the lead electrode assembly 100 from sliding
20 toward the distal end 1151 of the pair of tines 1151 of the rail fork 1146.

As discussed with reference to FIG. 32(c), the lead electrode assembly manipulation tool 927 may then be used to place the lead electrode assembly 100 into the incision 905 of
25 the patient 900 and used to move the electrode 107 to the termination point 1085 of the subcutaneous path 1090.

The lead electrode assembly 100 is then released from the lead electrode assembly manipulation tool 927. To achieve this,

5 the lead 21 of the lead electrode assembly 100 is released so
that the pair of tines 1151 of the rail fork 1146 of the lead
electrode assembly manipulation tool 927 can slide relative to
the rail 1100 of the lead electrode assembly 100. The lead
electrode assembly manipulation tool 927 may then be extracted
10 from the subcutaneous path 1090, leaving the lead electrode
assembly 100 behind.

FIGS. 36(a)-36(b) illustrate an alternative embodiment of
the lead electrode assembly 100. This embodiment is
substantially similar to the embodiments illustrated in FIGS.
15 17(a)-17(g). The backing layer 130 of this embodiment, however,
lacks an integrated fin tab 180. Moreover, the lead electrode
assembly 100 of this embodiment further comprises a pocket 1300.

FIG. 36(a) illustrates a cross-sectional side plan view of
this embodiment. The pocket 1300 comprises a layer of material
1315 and stitching 360. The pocket further comprises an
20 interior 1305 and an opening 1310. The layer of material 1315
is attached to the molded cover 220 with the stitching 360. The
molded cover 220 is, in turn, attached to the electrode 107.

The molded cover 220 comprises an outer surface 1330 and a
25 top surface 1331. The outer surface 1330 of the molded cover
220 is the surface of the molded cover 220 that does not lie
adjacent to the backing layer 131 or the electrode 107. The top

5 surface 1331 of the molded cover 220 faces away from, and parallel to the electrode 107.

10 The layer of material 1315 of the pocket 1300 comprises an inner face 1316 and an outer face 1317. The layer of material 1315 is attached to the top surface 1331 of the molded cover 220 so that the inner face 1316 of the layer of material 1315 faces the top surface 1331 of the molded cover 220. The inner face 1316 of the layer of material 1315 also faces the top surface 110 of the electrode 107.

15 The layer of material 1315 is made of polyurethane. In other embodiments, the layer of material 1315 is made of any bio-compatible material suitable for this purpose. In other embodiments, the layer of material 1315 is made of any bio-compatible polymeric material.

20 The stitching 360 fastening the layer of material 1315 to the top surface 1331 of the molded cover 220 is comprised of nylon. In alternate embodiments, the stitching 360 comprises any polymeric material.

25 FIG. 36(b) illustrates a top plan view of the lead electrode assembly 100 of FIG. 36(a). The top surface 1331 of the molded cover 220 has a first side 1333, a second side 1334, a distal end 1336, a proximal end 1337, a length and a width.

The distal end 1336, proximal end 1337, first side 1333 and second side 1334 of the top surface 1331 of the molded cover 220

5 are positioned substantially over the distal end 137 (phantom view), proximal end 138 (phantom view), first side 133 (not shown) and second side 134 (not shown) of the backing layer 130 (phantom view) respectively.

10 The width of the top surface 1331 of the molded cover 220 is measured as the distance between the first side 1333 and second side 1334 of the back surface. The length of the top surface 1331 of the molded cover is measured as the distance between the distal end 1336 and proximal end 1337 of the molded cover 220.

15 The layer of material 1315 comprises a periphery 1318 and a middle portion 1319. More particularly, the layer of material 1315 comprises a distal end 1320, a proximal end 1321, a first side 1322 and a second side 1323. The periphery 1318 of the layer of material 1315 comprises the distal end 1320, the proximal end 1321, the first side 1322 and the second side 1323 of the layer of material 1315. The middle portion 1319 of the layer of material 1315 comprises the area between the distal end 1320, the proximal end 1321, the first side 1322 and the second side 1323 of the layer of material 1315.

25 The pocket 1300 formed by the layer of material 1315 further comprises a bounded region 1325 and a center 1326. The bounded region 1325 of the pocket 1300 is attached to the back face 1317 of the molded cover 220. The center 1326 of the

5 pocket 1300 is not attached to the back face 1317 of the molded cover 220. Stitching 360 in the bounded region 1325 is used to attach the layer of material 1315 to the molded cover 220.

In the embodiment under discussion, the bounded region 1325 of the pocket 1300 comprises a portion of the periphery 1318 of the layer of material 1315. The bounded region 1325 of the pocket 1300 comprises the proximal end 1321, the first side 1322 and the second side 1323 of the layer of material 1315. In this embodiment, the bounded region 1325 of the pocket 1300 does not comprise the distal end 1320 of the layer of material 1315. The center 1326 of the pocket 1300 comprises the middle portion 1319 of the layer of material 1315. The bounded region 1325 is curved around the center 1326 of the pocket 1300 in a "U" shape. The bounded region 1325 of the pocket 1300 does not completely enclose the center 1326 of the pocket 1300.

In this embodiment, the bounded region 1325 of the pocket comprises a contiguous portion of the periphery 1318 of the layer of material 1315. In an alternate embodiment, the bounded region 1325 of the pocket comprises a plurality of segmented portions of the periphery 1318 of the layer of material 1315.

In an alternate embodiment the bounded region 1325 of the pocket 1300 does not comprise any portion of the periphery 1318 of the layer of material 1315. In alternate embodiments, the bounded region 1325 comprises any shape that could be traced on

5 the layer of material 1315 that partially encloses a center
1326. In one embodiment, the bounded region 1325 of the pocket
1300 is a portion of a circle's circumference (not shown) that
does not touch the periphery 1318 of the layer of material 1315.
The center 1326 is the area inside the circle.

10 In an alternate embodiment, the pocket 1300 comprises a
sheet of molded silicone. The molded silicone is fused to the
molded cover 220 in the bounded region 1325.

15 The opening 1310 of the pocket 1300 comprises the area
between the distal end 1320 of the layer of material 1315 and
the top surface 1331 of the molded cover 220. The interior 1305
of the pocket 1300 comprises the area between the middle portion
1319 of the layer of material 1315 and the top surface 1331 of
the molded cover 220.

20 The layer of material 1315 is positioned so that its first
side 1322 and second side 1323 are positioned over the first
side 1333 and second side 1334 of the top surface 1331 of the
molded cover 220 respectively. The layer of material 1315 is
positioned so that its proximal end 1321 is positioned over the
proximal end 1337 of the top surface 1331 of the molded cover
25 220.

The layer of material 1315 is sized so that its length is
shorter than the length of the top surface 1331 of the molded
cover 220. In alternate embodiments, the layer of material 1315

5 is sized so that its length is equal to, or longer than the length of the top surface 1331 of the molded cover 220.

The proximal end 1321 of the layer of material 1315 is sized so that its width is substantially equal to the width of the proximal end 1337 of the top surface 1331 of the molded
10 cover 220. The layer of material 1315 is sized so that its width steadily increases toward its distal end 1320.

The first side 1318 of the distal end 1320 of the layer of material 1315 is fastened to the first side 1333 of the top surface 1331 of the molded cover 220. The second side 1323 of
15 the distal end 1320 of the layer of material 1315 is fastened to the second side 1334 of the top surface 1331 of the molded cover 220.

Since the first end 1322 of the layer of material 1315 is wider than the top surface 1331 of the molded cover 220, the
20 layer of material 1315 separates from the top surface 1331 of the molded cover 220 to form the interior 1305 of the pocket 1300.

In an alternate embodiment, the lead electrode assembly 100 lacks a molded cover 220 and the pocket 1300 is attached
25 directly to the backing layer 130. In another alternate embodiment the lead electrode assembly 100 lacks a molded cover 220 and a backing layer 130 and the pocket 1300 is attached directly to the electrode 107. In a further alternate

5 embodiment, the pocket 1300 is molded as part of the molded cover 220.

FIG. 36(c) illustrates a cross-sectional side plan view of an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiment
10 illustrated in FIGS. 36(a)-36(b). The backing layer 130 of this embodiment, however, further comprises a fin 120 positioned in the interior 1305 of the pocket 1300. The fin 120 of this embodiment is substantially similar to the fin 120 of the embodiment illustrated in FIG. 17(b).

15 The fin 120 comprises an integrated fin tab 180 formed on the backing layer 130. The molded cover 220 covers the integrated fin tab 180 to form the fin 120. The integrated fin tab 180 has a slope-shaped proximal edge 183. The sloped-shape of the resulting fin 120 permits a the fin 120 to fit deeply
20 into the interior 1305 of the pocket 1300. The hood can act to reduce the resistance presented by the tissues of the patient against the fin 120 and any tool used to grasp the fin 120 during insertion of the lead electrode assembly 100. Such a hood can be placed over any fin discussed in the specification
25 to perform this function or any other function.

In alternate embodiments, appendages other than a fin are positioned between the pocket 1300 and the electrode 107, in the interior 1305 of the pocket 1300. In one embodiment, a loop

5 such as that discussed with reference to FIGS. 21(a)-21(c) is positioned in the interior 1305 of the pocket 1300. In another embodiment, a tube such as that discussed with reference to FIG. 26 is positioned in the interior 1305 of the pocket 1300.

FIG. 37(a) and 37(b) illustrates an alternate embodiment of
10 the lead electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIGS. 36(a)-36(b).

FIG. 37(a) illustrates a bottom plan view of the lead
15 electrode assembly 100 of this embodiment. In this embodiment, the electrode 107 is thumbnail shaped.

FIG. 37(b) illustrates a top plan view of the lead
electrode assembly 100 of this embodiment. The top surface 1331 of the molded cover 220 is shaped to accommodate the thumbnail shaped electrode 107.

20 Like the embodiment discussed with reference to FIGS. 36(a) and 36(b), the pocket 1300 comprises a layer of material 1315. In this embodiment, however, the layer of material 1315 has a roughly triangular shape. The layer of material 1315 comprises a periphery 1318 and a middle portion 1319. More particularly,
25 the layer of material comprises a first side 1340, a second side 1341 and a third side 1342 of the layer of material 1315. The periphery 1318 of the layer of material comprises the first side 1340, the second side 1341 and the third side 1342 of the layer

5 of material 1315. The middle portion 1319 of the layer of material 1315 comprises the area between the first side 1340, the second side 1341 and the third side 1342 of the layer of material 1315.

10 In this embodiment, the bounded region 1325 of the pocket 1300 comprises a portion of the periphery 1318 of the layer of material 1315. The bounded region 1325 of the pocket 1300 comprises the first side 1340 and the second side 1341 of the layer of material 1315. The center 1326 of the pocket 1300 comprises the middle portion 1319 of the layer of material 1315. The opening 1310 of the pocket 1300 comprises the third side 1342 of the layer of material 1315 and the top surface 1331 of the molded cover 220. The bounded region 1325 of the pocket 1300 is curved around the center 1326 of the pocket 1300. The bounded region 1325 of the pocket 1300 does not completely
20 enclose the center 1326.

In this embodiment, the bounded region 1325 of the pocket comprises a contiguous portion of the periphery 1318 of the layer of material 1315. In an alternate embodiment, the bounded region 1325 of the pocket comprises a plurality of segmented
25 portions of the periphery 1318 of the layer of material 1315.

In an alternate embodiment the bounded region 1325 of the pocket 1300 does not comprise any portion of the periphery 1318 of the layer of material 1315.

5 FIG. 38(a)-38(c) illustrates a lead electrode assembly manipulation tool 927. The lead electrode assembly manipulation tool 927 illustrated is useful for manipulating a lead electrode assembly 100 having a pocket 1300 during the implantation of the lead electrode assembly 100 in a patient. Examples of such a
10 lead electrode assembly 100 embodiments are shown in FIGS. 36(a), 36(b), 37(a) and 37(b).

FIG. 38(a) is a top view of the lead electrode assembly manipulation tool 927 of this embodiment. The lead electrode assembly manipulation tool 927 comprises a handle 1142 (not
15 shown), a rod 1144 and a paddle 1350.

The rod 1144 and handle 1142 are substantially similar to the rod 1144 and handle 1142 of the lead electrode assembly manipulation tool 927 illustrated in FIGS. 35(a)-35(d). The handle 1142 is connected to the rod 1144.

20 The paddle 1350 is attached to the distal end 1148 of the rod 1144. The paddle 1350 comprises a disk 1351 and a tang 1161 (phantom view).

FIG. 38(b) is a side view of the lead electrode assembly manipulation tool 927 of this embodiment. The tang 1161 is
25 inserted in the slot 1162 in the rod 1144. The tang 1161 is welded into the slot 1162 of the rod 1144.

The disk 1351 and the tang 1161 are punched from a single sheet of steel having a thickness of approximately 3 mm. In

5 other embodiments, the disk 1351 and tang 1161 are composed of titanium, a polymeric material or any other material suitable for this purpose. In one embodiment, the handle 1142, the rod 1144 and the paddle 1350 are all made from the same piece of material.

10 We now turn to FIG. 38(c) for a description of the use of the lead electrode assembly manipulation tool 927 in the implantation of a lead electrode assembly 100 into a patient.

As discussed with reference to FIG. 31, an incision 905 is made in the patient 900. As discussed with reference to FIG. 15 32(a), a subcutaneous path 1090 is created in the patient 900 with a hemostat 932.

10 20 The lead electrode assembly 100 is then captured by the lead electrode assembly manipulation tool 927. The paddle 1350 of the lead electrode assembly manipulation tool 927 is inserted into the pocket 1300 of the lead electrode assembly 100. The paddle 1350 is slid into the interior 1305 of the pocket via the opening 1310 of the pocket until it can go no further. At this point, the paddle 1350 touches the inner surface 1316 of the proximal end 1321 of the layer of material 1315.

25 The lead 21 of the lead electrode assembly 100 can then be pulled toward the handle 1142 of the lead electrode assembly manipulation tool 927 until it is taught. This acts to prevent the paddle 1350 of the lead electrode assembly manipulation tool

5 927 from sliding out of the pocket 1300 of the lead electrode assembly 100.

The lead electrode assembly manipulation tool 927 may then be used to place the lead electrode assembly 100 into the incision 905 of the patient as seen in FIG. 31. The lead
10 electrode assembly manipulation tool 927 may then be used to move the electrode 107 to the termination point 1085 of the subcutaneous path 1090 created as discussed with reference to FIG. 32(c).

15 The lead electrode assembly 100 is then released from the lead electrode assembly manipulation tool 927. To achieve this, the lead 21 of the lead electrode assembly 100 is released so that the paddle 1350 can slide relative to the pocket 1300 of the lead electrode assembly 100. The lead electrode assembly manipulation tool 927 may then be extracted from the
20 subcutaneous path 1090 leaving the lead electrode assembly 100 behind.

Alternately, a curved hemostat, such as the hemostat 930 discussed with reference to FIG. 32(b) could be inserted in the pocket 1300 of the lead electrode assembly 100. The hemostat
25 could then be used to move the electrode 107 to the termination point 1085 of the subcutaneous path 1090 as discussed above.

Alternately, a curved hemostat, such as the hemostat 930 discussed with reference to FIG. 32(b) could be used to grip the

5 pocket 1300 of the lead electrode assembly 100, and used to move the electrode 107 to the termination point 1085 of the subcutaneous path 1090 as discussed above.

FIGS. 39(a)-39(b) illustrate an alternative embodiment of the lead electrode assembly 100. This embodiment is substantially similar to the embodiment illustrated in FIGS. 38(a)-38(c). The backing layer 130 of this embodiment, however, lacks a pocket 1300. Moreover, the lead electrode assembly 100 of this embodiment further comprises a first channel guide 1401 and a second channel guide 1402.

15 FIG 39(a) illustrates a cross-sectional rear plan view of the lead electrode assembly 100 of this embodiment. The first channel guide 1401 and a second channel guide 1402 each have an interior 1403 and an opening 1404.

The first channel guide 1401 and the second channel guide 1402 each comprise a strip of material 1406 attached to the molded cover 220.

The strip of material 1406 comprising the first channel guide 1401 is substantially rectangular in shape. The strip of material 1406 comprises a first side 1410 and a second side 1412. The first side 1410 and the second side 1412 of the strip of material 1406 are parallel to each other. In another embodiment, the first side 1410 of the strip of material 1406 is not parallel to the second side 1412.

5 The strip of material 1406 further comprises an inner
surface 1417 and a outer surface 1416. The strip of material is
positioned so that the inner surface 1417 of the first side 1410
faces the outer surface 1330 of the molded cover 220. The first
side 1410 of the strip of material is attached to the first side
10 1333 of the top surface 1331 of the molded cover 220. The
second side 1412 of the strip of material 1406 is attached to
the skirt 222 of the molded cover 220.

15 The interior 1403 of the first channel guide is formed
between the inner face 1417 of the strip of material 1406 and
the outer surface 1330 of the molded cover 220.

20 The second channel guide is formed in substantially the
same way on the second side 1334 of the molded cover 220.

25 FIG. 39(b) illustrates a top plan view of the lead
electrode assembly of the embodiment of FIG. 39(a). The strip
of material 1406 comprising the first channel guide 1401 is
substantially rectangular in shape having a distal end 1413 and
a proximal end 1414. The distal end 1413 and the proximal end
1414 of the strip of material 1406 are parallel to each other.
In another embodiment, the distal end 1413 of the strip of
material 1406 is not parallel to the proximal end 1414 of the
strip of material 1406.

5 The opening 1404 of the first channel guide 1401 is formed by the distal end 1413 of the strip of material 1406 and the outer surface 1330 of the molded cover 220.

10 The first side 1410 and the second side 1412 (not shown) of the strip of material 1406 comprising the first channel guide 1401 are positioned so that they lie parallel to the first side 1333 (phantom view) of the molded cover 220.

15 The second channel guide 1402 is formed and mounted to the lead electrode assembly 100 in substantially the same way as the first channel guide 1401. The first side 1410 and the second side 1412 (not shown) of the strip of material 1406 comprising the second channel guide 1402 are positioned so that they lie parallel to the second side 1333 (phantom view) of the molded cover 220.

20 The strips of material 1406 are composed of polyurethane. In an alternate embodiment, the strips of material 1406 are composed of any polymeric material. The strips of material 1406 are fastened to the molded cover 220 with stitching 360.

25 In an alternate embodiment, the strips of material 1406 are made of molded silicone and attached to the molded cover 220 by fusing them to the molded cover 220. In an alternate embodiment, the first channel guide 1401 and the second channel guide 1402 are formed as part of the molded cover 220.

5 FIG. 40(a)-40(b) illustrates a lead electrode assembly manipulation tool 927. The lead electrode assembly manipulation tool 927 illustrated is useful for manipulating a lead electrode assembly 100 having a first channel guide 1401 and a second channel guide 1402 during the implantation of the lead electrode
10 assembly 100 in a patient. Examples of such a lead electrode assembly 100 embodiments are shown in FIGS. 39(a)-39(b).

FIG. 40(a) illustrates a top plan view of a lead electrode assembly manipulation tool 927. The lead electrode assembly manipulation tool 927 in this embodiment comprises a handle 1142
15 (not shown), a rod 1144 and a channel guide fork 1446.

The rod 1144 and handle 1142 are substantially similar to the rod 1144 and handle 1142 of the lead electrode assembly manipulation tool 927 illustrated in FIGS. 35(a)-35(d). The handle 1142 is connected to the rod 1144.

20 The channel guide fork 1446 is attached to the distal end 1148 of the rod 1144. The channel guide fork 1446 comprises a pair of tines 1451 separated by a gap 1455 and a tine base 1450 having a tang 1161.

25 The pair of tines 1451 each have a proximal end 1452 and a distal end 1453. The proximal ends 1452 of the pair of tines 1451 are attached to the tine base 1450. The pair of tines 1451 have a substantially cylindrical form. The distal end 1453 of each of the pair of tines 1451 is rounded.

5 The length of the pair of tines 1451 is substantially equal
to the length of the first side 1410 of the strips of material
1406 comprising the first channel guide 1401 and second channel
guide 1402. In alternate embodiments, the length of the tines
1451 is substantially greater than or less than the length of
10 the first side 1410 of the strips of material 1406 comprising
the first channel guide 1401 and second channel guide 1402.

The tines are separated by a gap 1455 between the proximal
ends 1452 of the pair of tines 1451. The pair of tines 1451 are
substantially straight and substantially parallel to each other.

15 The tine base 1450 connects the pair of tines 1451 to the
distal end 1148 of the rod 1144. The tine base 1450 comprises a
tang 1161 (phantom view). The tang 1161 is inserted in a slot
1162 in the rod 1144. The tang 1161 is welded in the slot 1162
of the rod 1144.

20 The pair of tines 1451 comprising the channel guide fork
1446 are composed of steel and have a diameter of approximately
3 mm. The tine base 1450 comprising the channel guide fork 1446
is punched from a single strip of steel having a thickness of
approximately 3 mm. The pair of tines 1451 are welded to the
25 tine base 1450.

In other embodiments, the channel guide fork 1446 is
composed of metal, a polymeric material, or any other material
suitable for this purpose. In one embodiment, the handle 1142,

5 the rod 1144 and the channel guide fork 1446 are all made from the same piece of material.

We now turn to FIG. 40(b) for a description of the use of the lead electrode assembly manipulation tool 927 in the implantation of a lead electrode assembly 100 into a patient.

10 As discussed with reference to FIG. 31, an incision 905 is made in the patient 900. As discussed with reference to FIG. 32(a), a subcutaneous path 1090 is created in the patient 900 with a hemostat 932.

15 The lead electrode assembly 100 is then captured by the lead electrode assembly manipulation tool 927. The pair of tines 1451 of the lead electrode assembly manipulation tool 927 is inserted into the openings 1404 in the first channel guide 1401 and second channel guide 1402.

20 The electrode 107 is placed into the gap 1455 between the tines of the channel guide fork 1446. The tines 1451 fit into the interior 1403 of the first channel guide 1401 and second channel guide 1402. The molded cover is slid toward the proximal end 1452 of the tines until it can go no further. The lead 21 of the lead electrode assembly 100 can then be pulled in
25 toward the handle 1142 of the lead electrode assembly manipulation tool 927 until it is taught. This acts to prevent the lead electrode assembly 100 from sliding toward the distal

5 end 1453 of the pair of tines 1451 of the channel guide fork 1446.

The lead electrode assembly manipulation tool 927 may then be used to place the lead electrode assembly 100 into the incision 905 of the patient as seen in FIG. 31. The lead
10 electrode assembly manipulation tool 927 may then be used to move the electrode 107 through the termination point 1085 of the subcutaneous path 1090 created as discussed with reference to FIG. 32(c).

The lead electrode assembly 100 is then released from the
15 lead electrode assembly manipulation tool 927. To achieve this, the lead 21 of the lead electrode assembly 100 is released so that the pair of tines 1451 of the channel guide fork 1446 of the lead electrode assembly manipulation tool 927 can slide relative to the first channel guide 1401 and second channel
20 guide 1402 of the lead electrode assembly 100. The lead electrode assembly manipulation tool 927 may then be extracted from the subcutaneous path 1090 leaving the lead electrode assembly 100 behind.

FIG. 41(a) illustrates a subcutaneous implantable
25 cardioverter-defibrillator kit 1201 of the present invention.

The kit comprises a group of items that may be used in implanting a S-ICD system in a patient. The kit 1201 comprises a group of one or more of the following items: an S-ICD canister

5 11, a lead electrode assembly 100, a hemostat 1205, a lead
electrode assembly manipulation tool 927, a medical adhesive
1210, an anesthetic 1215, a tube of mineral oil 1220 and a tray
1200 for storing these items.

10 In one embodiment, the S-ICD canister 11 is the S-ICD
canister 11 seen in, and discussed with reference to FIG. 1.

15 The lead electrode assembly 100 is the lead electrode
assembly 100 with a rail 1100, and discussed with reference to
FIGS. 33(b) and 33(c). In alternate embodiments, the lead
electrode assembly 100 is any lead electrode assembly 100
including an electrode 107 with an appendage 118; a pocket; or a
first and second channel guide for positioning the electrode 107
during implantation.

20 The hemostat 1205 is a curved hemostat made of steel having
a first end 1240 and a second end 1241. The hemostat 1205 has a
length, measured between the first end 1240 and the second end
1241 as shown in FIG. 41(b) by dimension L_{Hemostat} . The length of
the hemostat 1205, L_{Hemostat} , is approximately 75 cm. In an
alternate embodiments, the hemostat 1205 is a length other than
75 cm. In an alternate embodiment, the hemostat 1205 is the
25 enhanced hemostat seen in, and discussed with reference to FIG.
31.

The lead electrode assembly manipulation tool 927 is the
lead electrode assembly manipulation tool 927 with a rail fork

5 1146. In alternate embodiments, the lead electrode assembly manipulation tool 927 is any lead electrode assembly manipulation tool 927 including a paddle or a channel guide fork.

10 The medical adhesive 1210 comprises a roll of clear, 1-inch wide medical adhesive tape. As will be recognized, the medical adhesive could be a liquid adhesive, or any other adhesive substance.

15 The anesthetic 1215 is a one ounce tube of lidocaine gel. This can be used as a local anesthetic for the introduction of the lead electrode assembly 100 as discussed below. As will be recognized, the anesthetic could be any substance that has a pain-killing effect. Alternatively, one could use an injectable form of anesthetic inserted along the path of the lead.

20 The tube of mineral oil 1220 is a one ounce tube of mineral oil. This can be used for oiling parts of the electrode connector block 17 seen in FIG. 1.

25 The tray 1200 is a box sized to fit the items of the kit 1201. The tray 1200 is composed of molded plastic. In another embodiment, the tray 1200 is a cardboard box. One skilled in the art will recognize that the tray 1200 may comprise any container capable of containing the items of the kit. In one embodiment, the tray is formed with recessed partitions 1230 that generally follow the outline of the items of the kit 1201

5 to be stored in the tray. In one embodiment, the tray 1200 has packaging material 1225 disposed over it, wherein the packing material 1225 provides a sanitary cover for the items of the kit 1201. The packaging material 1225 further acts to contain the items of the kit 1201.

10 In an alternate embodiment the kit 1201 comprises ten lead electrode assemblies 100 each comprising a lead 21 having a lead length, l_{Lead} , different from the others. In one embodiment, the lead lengths range between approximately 5 cm and approximately 52 cm with approximately a 10 cm difference between the lead length of each lead electrode assembly 100.

15 In an alternative embodiment, the kit 1201 comprises an S-ICD canister 11, a hemostat 1205 and an assortment of lead electrode assemblies 100 each comprising a lead 21 having a lead length, l_{Lead} , different from the others.

20 In one embodiment, the kit 1200 further comprises a tray 1201 and an assortment of lead electrode assemblies 100, each with an electrode 107 curved at a radius r different from the others.

25 In another embodiment, the kit 1200 includes components sized for surgery on a patient of a particular size. A kit 1200 for a 10 year old child, for example, includes an S-ICD canister 11 with a length of approximately 10 cm, a lead electrode assembly 100 with a lead length, L_{Lead} of approximately 12 cm and

5 a radius r of approximately 10 cm and hemostat 1205 with a
hemostat length, L_{Hemostat} , of approximately 12 cm.

The S-ICD device and method of the present invention may be
embodied in other specific forms without departing from the
teachings or essential characteristics of the invention. The
10 described embodiments are therefore to be considered in all
respects as illustrative and not restrictive, the scope of the
invention being indicated by the appended claims rather than by
the foregoing description and all changes which come within the
meaning and range of equivalency of the claims are therefore to
15 be embraced therein.
